FANUC Series Oi-MODEL D

FANUC Series Oi Mate-MODEL D

For Lathe System

USER’S MANUAL
• No part of this manual may be reproduced in any form.
• All specifications and designs are subject to change without notice.

The products in this manual are controlled based on Japan’s “Foreign Exchange and Foreign Trade Law”. The export from Japan may be subject to an export license by the government of Japan.
Further, re-export to another country may be subject to the license of the government of the country from where the product is re-exported. Furthermore, the product may also be controlled by re-export regulations of the United States government.
Should you wish to export or re-export these products, please contact FANUC for advice.

In this manual we have tried as much as possible to describe all the various matters. However, we cannot describe all the matters which must not be done, or which cannot be done, because there are so many possibilities.
Therefore, matters which are not especially described as possible in this manual should be regarded as “impossible”.

This manual contains the program names or device names of other companies, some of which are registered trademarks of respective owners. However, these names are not followed by ® or ™ in the main body.
SAFETY PRECAUTIONS

This section describes the safety precautions related to the use of CNC units.

It is essential that these precautions be observed by users to ensure the safe operation of machines equipped with a CNC unit (all descriptions in this section assume this configuration). Note that some precautions are related only to specific functions, and thus may not be applicable to certain CNC units.

Users must also observe the safety precautions related to the machine, as described in the relevant manual supplied by the machine tool builder. Before attempting to operate the machine or create a program to control the operation of the machine, the operator must become fully familiar with the contents of this manual and relevant manual supplied by the machine tool builder.

CONTENTS

DEFINITION OF WARNING, CAUTION, AND NOTE ................s-2
GENERAL WARNINGS AND CAUTIONS....................................s-3
WARNINGS AND CAUTIONS RELATED TO
PROGRAMMING .............................................................................s-6
WARNINGS AND CAUTIONS RELATED TO HANDLING........s-9
WARNINGS RELATED TO DAILY MAINTENANCE .................s-12
DEFINITION OF WARNING, CAUTION, AND NOTE

This manual includes safety precautions for protecting the user and preventing damage to the machine. Precautions are classified into **Warning** and **Caution** according to their bearing on safety. Also, supplementary information is described as a **Note**. Read the **Warning**, **Caution**, and **Note** thoroughly before attempting to use the machine.

**WARNING**
Applied when there is a danger of the user being injured or when there is a danger of both the user being injured and the equipment being damaged if the approved procedure is not observed.

**CAUTION**
Applied when there is a danger of the equipment being damaged, if the approved procedure is not observed.

**NOTE**
The Note is used to indicate supplementary information other than Warning and Caution.

- Read this manual carefully, and store it in a safe place.
GENERAL WARNINGS AND CAUTIONS

⚠️ WARNING

1. Never attempt to machine a workpiece without first checking the operation of the machine. Before starting a production run, ensure that the machine is operating correctly by performing a trial run using, for example, the single block, feedrate override, or machine lock function or by operating the machine with neither a tool nor workpiece mounted. Failure to confirm the correct operation of the machine may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

2. Before operating the machine, thoroughly check the entered data. Operating the machine with incorrectly specified data may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

3. Ensure that the specified feedrate is appropriate for the intended operation. Generally, for each machine, there is a maximum allowable feedrate. The appropriate feedrate varies with the intended operation. Refer to the manual provided with the machine to determine the maximum allowable feedrate. If a machine is run at other than the correct speed, it may behave unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

4. When using a tool compensation function, thoroughly check the direction and amount of compensation. Operating the machine with incorrectly specified data may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.
WARNING
5 The parameters for the CNC and PMC are factory-set. Usually, there is not need to change them. When, however, there is not alternative other than to change a parameter, ensure that you fully understand the function of the parameter before making any change. Failure to set a parameter correctly may result in the machine behaving unexpectedly, possibly causing damage to the workpiece and/or machine itself, or injury to the user.

6 Immediately after switching on the power, do not touch any of the keys on the MDI panel until the position display or alarm screen appears on the CNC unit. Some of the keys on the MDI panel are dedicated to maintenance or other special operations. Pressing any of these keys may place the CNC unit in other than its normal state. Starting the machine in this state may cause it to behave unexpectedly.

7 The User’s Manual and programming manual supplied with a CNC unit provide an overall description of the machine's functions, including any optional functions. Note that the optional functions will vary from one machine model to another. Therefore, some functions described in the manuals may not actually be available for a particular model. Check the specification of the machine if in doubt.

8 Some functions may have been implemented at the request of the machine-tool builder. When using such functions, refer to the manual supplied by the machine-tool builder for details of their use and any related cautions.

CAUTION
The liquid-crystal display is manufactured with very precise fabrication technology. Some pixels may not be turned on or may remain on. This phenomenon is a common attribute of LCDs and is not a defect.
Programs, parameters, and macro variables are stored in nonvolatile memory in the CNC unit. Usually, they are retained even if the power is turned off. Such data may be deleted inadvertently, however, or it may prove necessary to delete all data from nonvolatile memory as part of error recovery. To guard against the occurrence of the above, and assure quick restoration of deleted data, backup all vital data, and keep the backup copy in a safe place.
WARNINGS AND CAUTIONS RELATED TO PROGRAMMING

This section covers the major safety precautions related to programming. Before attempting to perform programming, read the supplied User’s Manual carefully such that you are fully familiar with their contents.

⚠️ WARNING

1. Coordinate system setting
   If a coordinate system is established incorrectly, the machine may behave unexpectedly as a result of the program issuing an otherwise valid move command. Such an unexpected operation may damage the tool, the machine itself, the workpiece, or cause injury to the user.

2. Positioning by nonlinear interpolation
   When performing positioning by nonlinear interpolation (positioning by nonlinear movement between the start and end points), the tool path must be carefully confirmed before performing programming. Positioning involves rapid traverse. If the tool collides with the workpiece, it may damage the tool, the machine itself, the workpiece, or cause injury to the user.

3. Function involving a rotation axis
   When programming polar coordinate interpolation, pay careful attention to the speed of the rotation axis. Incorrect programming may result in the rotation axis speed becoming excessively high, such that centrifugal force causes the chuck to lose its grip on the workpiece if the latter is not mounted securely. Such mishap is likely to damage the tool, the machine itself, the workpiece, or cause injury to the user.

4. Inch/metric conversion
   Switching between inch and metric inputs does not convert the measurement units of data such as the workpiece origin offset, parameter, and current position. Before starting the machine, therefore, determine which measurement units are being used. Attempting to perform an operation with invalid data specified may damage the tool, the machine itself, the workpiece, or cause injury to the user.
WARNING

5 Constant surface speed control
When an axis subject to constant surface speed control approaches the origin of the workpiece coordinate system, the spindle speed may become excessively high. Therefore, it is necessary to specify a maximum allowable speed. Specifying the maximum allowable speed incorrectly may damage the tool, the machine itself, the workpiece, or cause injury to the user.

6 Stroke check
After switching on the power, perform a manual reference position return as required. Stroke check is not possible before manual reference position return is performed. Note that when stroke check is disabled, an alarm is not issued even if a stroke limit is exceeded, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the user.

7 Interference check for each path
An interference check for each path is performed based on the tool data specified during automatic operation. If the tool specification does not match the tool actually being used, the interference check cannot be made correctly, possibly damaging the tool or the machine itself, or causing injury to the user. After switching on the power, or after selecting a tool post manually, always start automatic operation and specify the tool number of the tool to be used.

8 Absolute/incremental mode
If a program created with absolute values is run in incremental mode, or vice versa, the machine may behave unexpectedly.

9 Plane selection
If an incorrect plane is specified for circular interpolation, helical interpolation, or a canned cycle, the machine may behave unexpectedly. Refer to the descriptions of the respective functions for details.

10 Torque limit skip
Before attempting a torque limit skip, apply the torque limit. If a torque limit skip is specified without the torque limit actually being applied, a move command will be executed without performing a skip.
**WARNING**

11 Compensation function

If a command based on the machine coordinate system or a reference position return command is issued in compensation function mode, compensation is temporarily canceled, resulting in the unexpected behavior of the machine. Before issuing any of the above commands, therefore, always cancel compensation function mode.
WARNINGS AND CAUTIONS RELATED TO HANDLING

This section presents safety precautions related to the handling of machine tools. Before attempting to operate your machine, read the supplied User’s Manual carefully, such that you are fully familiar with their contents.

⚠️ WARNING

1. **Manual operation**
   When operating the machine manually, determine the current position of the tool and workpiece, and ensure that the movement axis, direction, and feedrate have been specified correctly. Incorrect operation of the machine may damage the tool, the machine itself, the workpiece, or cause injury to the operator.

2. **Manual reference position return**
   After switching on the power, perform manual reference position return as required. If the machine is operated without first performing manual reference position return, it may behave unexpectedly. Stroke check is not possible before manual reference position return is performed. An unexpected operation of the machine may damage the tool, the machine itself, the workpiece, or cause injury to the user.

3. **Manual handle feed**
   In manual handle feed, rotating the handle with a large scale factor, such as 100, applied causes the tool and table to move rapidly. Careless handling may damage the tool and/or machine, or cause injury to the user.

4. **Disabled override**
   If override is disabled (according to the specification in a macro variable) during threading, rigid tapping, or other tapping, the speed cannot be predicted, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the operator.

5. **Origin/preset operation**
   Basically, never attempt an origin/preset operation when the machine is operating under the control of a program. Otherwise, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the tool, or causing injury to the user.
**WARNING**

6 **Workpiece coordinate system shift**

Manual intervention, machine lock, or mirror imaging may shift the workpiece coordinate system. Before attempting to operate the machine under the control of a program, confirm the coordinate system carefully.

If the machine is operated under the control of a program without making allowances for any shift in the workpiece coordinate system, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the operator.

7 **Software operator's panel and menu switches**

Using the software operator's panel and menu switches, in combination with the MDI panel, it is possible to specify operations not supported by the machine operator's panel, such as mode change, override value change, and jog feed commands.

Note, however, that if the MDI panel keys are operated inadvertently, the machine may behave unexpectedly, possibly damaging the tool, the machine itself, the workpiece, or causing injury to the user.

8 **RESET key**

Pressing the RESET key stops the currently running program. As a result, the servo axes are stopped. However, the RESET key may fail to function for reasons such as an MDI panel problem. So, when the motors must be stopped, use the emergency stop button instead of the RESET key to ensure security.

9 **Manual intervention**

If manual intervention is performed during programmed operation of the machine, the tool path may vary when the machine is restarted. Before restarting the machine after manual intervention, therefore, confirm the settings of the manual absolute switches, parameters, and absolute/incremental command mode.

10 **Feed hold, override, and single block**

The feed hold, feedrate override, and single block functions can be disabled using custom macro system variable #3004. Be careful when operating the machine in this case.
\section*{\textbf{WARNING}}

\textbf{11 Dry run} \\
Usually, a dry run is used to confirm the operation of the machine. During a dry run, the machine operates at dry run speed, which differs from the corresponding programmed feedrate. Note that the dry run speed may sometimes be higher than the programmed feed rate.

\textbf{12 Program editing} \\
If the machine is stopped, after which the machining program is edited (modification, insertion, or deletion), the machine may behave unexpectedly if machining is resumed under the control of that program. Basically, do not modify, insert, or delete commands from a machining program while it is in use.
WARNINGS RELATED TO DAILY MAINTENANCE

**WARNING**

1. **Memory backup battery replacement**

   When replacing the memory backup batteries, keep the power to the machine (CNC) turned on, and apply an emergency stop to the machine. Because this work is performed with the power on and the cabinet open, only those personnel who have received approved safety and maintenance training may perform this work.

   When replacing the batteries, be careful not to touch the high-voltage circuits (marked ⚠ and fitted with an insulating cover).

   Touching the uncovered high-voltage circuits presents an extremely dangerous electric shock hazard.

**NOTE**

The CNC uses batteries to preserve the contents of its memory, because it must retain data such as programs, offsets, and parameters even while external power is not applied.

If the battery voltage drops, a low battery voltage alarm is displayed on the machine operator's panel or screen.

When a low battery voltage alarm is displayed, replace the batteries within a week. Otherwise, the contents of the CNC's memory will be lost.

Refer to the Section “Method of replacing battery” in the User's Manual (Common to T/M series) for details of the battery replacement procedure.
2 Absolute pulse coder battery replacement

When replacing the memory backup batteries, keep the power to the machine (CNC) turned on, and apply an emergency stop to the machine. Because this work is performed with the power on and the cabinet open, only those personnel who have received approved safety and maintenance training may perform this work.

When replacing the batteries, be careful not to touch the high-voltage circuits (marked ⚠ and fitted with an insulating cover). Touching the uncovered high-voltage circuits presents an extremely dangerous electric shock hazard.

NOTE

The absolute pulse coder uses batteries to preserve its absolute position. If the battery voltage drops, a low battery voltage alarm is displayed on the machine operator's panel or screen.

When a low battery voltage alarm is displayed, replace the batteries within a week. Otherwise, the absolute position data held by the pulse coder will be lost.

Refer to the FANUC SERVO MOTOR αi series Maintenance Manual for details of the battery replacement procedure.
**WARNING**

3 Fuse replacement

Before replacing a blown fuse, however, it is necessary to locate and remove the cause of the blown fuse.

For this reason, only those personnel who have received approved safety and maintenance training may perform this work.

When replacing a fuse with the cabinet open, be careful not to touch the high-voltage circuits (marked \(\Delta\) and fitted with an insulating cover). Touching an uncovered high-voltage circuit presents an extremely dangerous electric shock hazard.

I. GENERAL
1

GENERAL

This manual consists of the following parts:

About this manual

I. GENERAL
   Describes chapter organization, applicable models, related
   manuals, and notes for reading this manual.

II. PROGRAMMING
   Describes each function: Format used to program functions in the
   NC language, characteristics, and restrictions.

III. OPERATION
   Describes the manual operation and automatic operation of a
   machine, procedures for inputting and outputting data, and
   procedures for editing a program.

APPENDIX
   Lists parameters, valid data ranges, and alarms.

NOTE
1. This manual describes the functions that can operate in the T series path control type. For other functions not specific to the T series, refer to the User's Manual (Common to Lathe System/Machining Center System) (B-64304EN).
2. Some functions described in this manual may not be applied to some products. For detail, refer to the DESCRIPTIONS manual (B-64302EN).
3. This manual does not detail the parameters not mentioned in the text. For details of those parameters, refer to the parameter manual (B-64310EN).
4. Parameters are used to set functions and operating conditions of a CNC machine tool, and frequently-used values in advance. Usually, the machine tool builder factory-sets parameters so that the user can use the machine tool easily.
5. This manual describes not only basic functions but also optional functions. Look up the options incorporated into your system in the manual written by the machine tool builder.

Special symbols

This manual uses the following symbols:

- **IP**
  
  Indicates a combination of axes such as X, Y, Z.  
  In the underlined position following each address, a numeric value such as a coordinate value is placed (used in PROGRAMMING.).

- **;**
  
  Indicates the end of a block. It actually corresponds to the ISO code LF or EIA code CR.

</tbody>
</table>

This manual mainly assumes that the FANUC SERVO MOTOR $\alpha_i$ series of servo motor is used. For servo motor and spindle information, refer to the manuals for the servo motor and spindle that are actually connected.
1.1 GENERAL FLOW OF OPERATION OF CNC MACHINE TOOL

When machining the part using the CNC machine tool, first prepare the program, then operate the CNC machine by using the program.

1. First, prepare the program from a part drawing to operate the CNC machine tool.
   How to prepare the program is described in the Part II, “Programming.”

2. The program is to be read into the CNC system. Then, mount the workpieces and tools on the machine, and operate the tools according to the programming. Finally, execute the machining actually.
   How to operate the CNC system is described in the Part III, “Operation.”

Before the actual programming, make the machining plan for how to machine the part.

Machining plan
1. Determination of workpieces machining range
2. Method of mounting workpieces on the machine tool
3. Machining sequence in every cutting process
4. Cutting tools and cutting conditions

Decide the cutting method in every cutting process.

</tbody>
</table>
Prepare the program of the tool path and cutting condition according to the workpiece figure, for each cutting.
1.2  NOTES ON READING THIS MANUAL

⚠️ CAUTION
1 The function of an CNC machine tool system depends not only on the CNC, but on the combination of the machine tool, its magnetic cabinet, the servo system, the CNC, the operator's panels, etc. It is too difficult to describe the function, programming, and operation relating to all combinations. This manual generally describes these from the stand-point of the CNC. So, for details on a particular CNC machine tool, refer to the manual issued by the machine tool builder, which should take precedence over this manual.
2 In the header field of each page of this manual, a chapter title is indicated so that the reader can reference necessary information easily. By finding a desired title first, the reader can reference necessary parts only.
3 This manual describes as many reasonable variations in equipment usage as possible. It cannot address every combination of features, options and commands that should not be attempted. If a particular combination of operations is not described, it should not be attempted.

1.3  NOTES ON VARIOUS KINDS OF DATA

⚠️ CAUTION
Machining programs, parameters, offset data, etc. are stored in the CNC unit internal non-volatile memory. In general, these contents are not lost by the switching ON/OFF of the power. However, it is possible that a state can occur where precious data stored in the non-volatile memory has to be deleted, because of deletions from a maloperation, or by a failure restoration. In order to restore rapidly when this kind of mishap occurs, it is recommended that you create a copy of the various kinds of data beforehand.
II. PROGRAMMING
Chapter 1, "GENERAL", consists of the following sections:

1.1 OFFSET ......................................................................................14
1.1 OFFSET

Explanation
- Tool offset

Usually, several tools are used for machining one workpiece. The tools have different tool length. It is very troublesome to change the program in accordance with the tools. Therefore, the length of each tool used should be measured in advance. By setting the difference between the length of the standard tool and the length of each tool in the CNC (see “Setting and Displaying Data” in the User’s Manual (Common to Lathe System/Machining Center System)), machining can be performed without altering the program even when the tool is changed. This function is called tool offset.

Fig. 1.1 (a) Tool offset
2. PREPARATORY FUNCTION (G FUNCTION)

A number following address G determines the meaning of the command for the concerned block. G codes are divided into the following two types.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>One-shot G code</td>
<td>The G code is effective only in the block in which it is specified.</td>
</tr>
<tr>
<td>Modal G code</td>
<td>The G code is effective until another G code of the same group is specified.</td>
</tr>
</tbody>
</table>

(Example)
- G01 and G00 are modal G codes in group 01.
  - G01 X_; Z_; X_; G01 is effective in this range.
  - G00 Z_; X_; G00 is effective in this range.
  - G01 X_; : |

There are three G code systems in the lathe system: A, B, and C (Table 2(a)). Select a G code system using bits 6 (GSB) and 7 (GSC) parameter No. 3401. Generally, User’s Manual describes the use of G code system A, except when the described item can use only G code system B or C. In such cases, the use of G code system B or C is described.
2. PREPARATORY FUNCTION
   (G FUNCTION)

Explanation

1. When the clear state (parameter CLR (No. 3402#6)) is set at power-up or reset, the modal G codes are placed in the states described below.
   (1) The modal G codes are placed in the states marked with ▲ as indicated in Table 2.
   (2) G20 and G21 remain unchanged when the clear state is set at power-up or reset.
   (3) Which status G22 or G23 at power on is set by parameter G23 (No. 3402#7). However, G22 and G23 remain unchanged when the clear state is set at reset.
   (4) The user can select G00 or G01 by setting parameter G01 (No. 3402#0).
   (5) The user can select G90 or G91 by setting parameter G91 (No. 3402#3).
      When G code system B or C is used in the lathe system, setting parameter G91 (No. 3402#3) determines which code, either G90 or G91, is effective.

2. G codes in group 00 other than G10 and G11 are one-shot G codes.

3. When a G code not listed in the G code list is specified, or a G code that has no corresponding option is specified, alarm PS0010 occurs.

4. Multiple G codes can be specified in the same block if each G code belongs to a different group. If multiple G codes that belong to the same group are specified in the same block, only the last G code specified is valid.

5. If a G code belonging to group 01 is specified in a for drilling, the canned cycle for drilling is cancelled. This means that the same state set by specifying G80 is set. Note that the G codes in group 01 are not affected by a G code specifying a canned cycle.

6. When G code system A is used, absolute or incremental programming is specified not by a G code (G90/G91) but by an address word (X/U, Z/W, C/H, Y/V). Only the initial level is provided at the return point of the canned cycle for drilling.

7. G codes are indicated by group.

Chapter 3, "INTERPOLATION FUNCTION", consists of the following sections:

3.1 POLAR COORDINATE INTERPOLATION (G12.1, G13.1)...21
3.2 CONSTANT LEAD THREADING (G32) .................................29
3.3 VARIABLE LEAD THREADING (G34) .................................33
3.4 CONTINUOUS THREADING..............................................34
3.5 MULTIPLE THREADING..................................................35
3.1 POLAR COORDINATE INTERPOLATION (G12.1, G13.1)

Overview

Polar coordinate interpolation is a function that exercises contour control in converting a command programmed in a Cartesian coordinate system to the movement of a linear axis (movement of a tool) and the movement of a rotary axis (rotation of a workpiece). This function is useful in cutting a front surface and grinding a cam shaft for turning.

Format

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G12.1;</td>
<td>Starts polar coordinate interpolation mode (enables polar coordinate interpolation). Specify linear or circular interpolation using coordinates in a Cartesian coordinate system consisting of a linear axis and rotary axis (hypothetical axis).</td>
</tr>
<tr>
<td>G13.1;</td>
<td>Polar coordinate interpolation mode is cancelled (for not performing polar coordinate interpolation). Specify G12.1 and G13.1 in Separate Blocks. G112 and G113 can be used in place of G12.1 and G13.1, respectively.</td>
</tr>
</tbody>
</table>

Explanation

- Polar coordinate interpolation mode (G12.1)

The axes of polar coordinate interpolation (linear axis and rotary axis) should be specified in advance, with corresponding parameters. Specifying G12.1 places the system in the polar coordinate interpolation mode, and selects a plane (called the polar coordinate interpolation plane) formed by one linear axis and a hypothetical axis intersecting the linear axis at right angles. The linear axis is called the first axis of the plane, and the hypothetical axis is called the second axis of the plane. Polar coordinate interpolation is performed in this plane.

In the polar coordinate interpolation mode, both linear interpolation and circular interpolation can be specified by absolute or incremental programming.

Tool nose radius compensation can also be performed. The polar coordinate interpolation is performed for a path obtained after tool nose radius compensation.

The tangential velocity in the polar coordinate interpolation plane (Cartesian coordinate system) is specified as the feedrate, using F.

- Polar coordinate interpolation cancel mode (G13.1)

Specifying G13.1 cancels the polar coordinate interpolation mode.
- Polar coordinate interpolation plane

G12.1 starts the polar coordinate interpolation mode and selects a polar coordinate interpolation plane (Fig. 3.1 (a)). Polar coordinate interpolation is performed on this plane.

![Diagram of polar coordinate interpolation plane](image)

When the power is turned on or the system is reset, polar coordinate interpolation is canceled (G13.1).

The linear and rotation axes for polar coordinate interpolation must be set in parameters Nos. 5460 and 5461 beforehand.

⚠️ CAUTION

The plane used before G12.1 is specified (plane selected by G17, G18, or G19) is canceled. It is restored when G13.1 (canceling polar coordinate interpolation) is specified.

When the system is reset, polar coordinate interpolation is canceled and the plane specified by G17, G18, or G19 is used.

- Distance moved and feedrate for polar coordinate interpolation

- The unit for coordinates on the hypothetical axis is the same as the unit for the linear axis (mm/inch).

In the polar coordinate interpolation mode, program commands are specified with Cartesian coordinates on the polar coordinate interpolation plane. The axis address for the rotary axis is used as the axis address for the second axis (hypothetical axis) in the plane. Whether a diameter or radius is specified for the first axis in the plane is the same as for the rotary axis regardless of the specification for the first axis in the plane.

The hypothetical axis is at coordinate 0 immediately after G12.1 is specified. Polar interpolation is started assuming the rotation angle of 0 for the position of the tool when G12.1 is specified.
Example)
When a value on the X-axis (linear axis) is input in millimeters
G12.1;
G01 X10. F1000. ; .. A 10-mm movement is made on the Cartesian coordinate system.
C20. ; .................... A 20-mm movement is made on the Cartesian coordinate system.
G13.1;

When a value on the X-axis (linear axis) is input in inches
G12.1;
G01 X10. F1000. ; .. A 10-inch movement is made on the Cartesian coordinate system.
C20. ; .................... A 20-inch movement is made on the Cartesian coordinate system.
G13.1;

- The unit for the feedrate is mm/min or inch/min.
  Specify the feedrate as a speed (relative speed between the workpiece and tool) tangential to the polar coordinate interpolation plane (Cartesian coordinate system) using F.

- G codes which can be specified in the polar coordinate interpolation mode
  G01 .......................Linear interpolation
  G02, G03...............Circular interpolation
  G04 .......................Dwell
  G40, G41, G42......Tool nose radius compensation
  (Polar coordinate interpolation is applied to the path after tool nose radius compensation.)
  G65, G66, G67......Custom macro command
  G90, G91...............Absolute programming, incremental programming
  (For G code system B or C)
  G98, G99..............Feed per minute, feed per revolution

- Circular interpolation in the polar coordinate plane
  The addresses for specifying the radius of an arc for circular interpolation (G02 or G03) in the polar coordinate interpolation plane depend on the first axis in the plane (linear axis).
  - I and J in the Xp-Yp plane when the linear axis is the X-axis or an axis parallel to the X-axis.
  - J and K in the Yp-Zp plane when the linear axis is the Y-axis or an axis parallel to the Y-axis.
  - K and I in the Zp-Xp plane when the linear axis is the Z-axis or an axis parallel to the Z-axis.
  The radius of an arc can be specified also with an R command.

NOTE
The parallel axes U, V, and W can be used in the G code system B or C.
- **Movement along axes not in the polar coordinate interpolation plane in the polar coordinate interpolation mode**

  The tool moves along such axes normally, independent of polar coordinate interpolation.

- **Current position display in the polar coordinate interpolation mode**

  Actual coordinates are displayed. However, the remaining distance to move in a block is displayed based on the coordinates in the polar coordinate interpolation plane (Cartesian coordinates).

- **Coordinate system for the polar coordinate interpolation**

  Basically, before G12.1 is specified, a local coordinate system (or workpiece coordinate system) where the center of the rotary axis is the origin of the coordinate system must be set. In the G12.1 mode, the coordinate system must not be changed (G50, G52, G53, relative coordinate reset, G54 through G59, etc.).

- **Compensation in the direction of the hypothetical axis in polar coordinate interpolation**

  If the first axis of the plane has an error from the center of the rotary axis in the hypothetical axis direction, in other words, if the rotary axis center is not on the X-axis, the hypothetical axis direction compensation function in the polar coordinate interpolation mode is used. With the function, the error is considered in polar coordinate interpolation. The amount of error is specified in parameter No. 5464.
- Shifting the coordinate system in polar coordinate interpolation

In the polar coordinate interpolation mode, the workpiece coordinate system can be shifted. The current position display function shows the position viewed from the workpiece coordinate system before the shift. The function to shift the coordinate system is enabled when bit 2 (PLS) of parameter No. 5450 is specified accordingly. The shift can be specified in the polar coordinate interpolation mode, by specifying the position of the center of the rotary axis C (A, B) in the X-C (Y-A, Z-B) interpolation plane with reference to the origin of the workpiece coordinate system, in the following format.

\[
\text{G12.1 X}_c \text{ C}_c ; \\
\text{G12.1 Y}_a \text{ A}_a ; \\
\text{G12.1 Z}_b \text{ B}_b ;
\]

(Polar coordinate interpolation for the X-axis and C-axis)
(Polar coordinate interpolation for the Y-axis and A-axis)
(Polar coordinate interpolation for the Z-axis and B-axis)

Limitation

- Changing the coordinate system during polar coordinate interpolation

In the G12.1 mode, the coordinate system must not be changed (G92, G52, G53, relative coordinate reset, G54 through G59, etc.).

- Tool nose radius compensation

The polar coordinate interpolation mode (G12.1 or G13.1) cannot be started or terminated in the tool nose radius compensation mode (G41 or G42). G12.1 or G13.1 must be specified in the tool nose radius compensation canceled mode (G40).

- Tool offset command

A tool offset must be specified before the G12.1 mode is set. No offset can be changed in the G12.1 mode.

- Program restart

For a block in the G12.1 mode, the program cannot be restarted.
- Cutting feedrate for the rotary axis

Polar coordinate interpolation converts the tool movement for a figure programmed in a Cartesian coordinate system to the tool movement in the rotary axis (C-axis) and the linear axis (X-axis). When the tool comes close to the center of the workpiece, the C-axis velocity component increases. If the maximum cutting feedrate for the C-axis (parameter No. 1430) is exceeded, the automatic feedrate override function and automatic speed clamp function are enabled.

If the maximum cutting feedrate for the X-axis is exceeded, the automatic feedrate override function and automatic speed clamp function are enabled.

⚠️ WARNING
Consider lines L1, L2, and L3. $\Delta X$ is the distance the tool moves per time unit at the feedrate specified with address F in the Cartesian coordinate system. As the tool moves from L1 to L2 to L3, the angle at which the tool moves per time unit corresponding to $\Delta X$ in the Cartesian coordinate system increases from $\theta_1$ to $\theta_2$ to $\theta_3$. In other words, the C-axis component of the feedrate becomes larger as the tool moves closer to the center of the workpiece. The C component of the feedrate may exceed the maximum cutting feedrate for the C-axis because the tool movement in the Cartesian coordinate system has been converted to the tool movement for the C-axis and the X-axis.

\[
F < L \times R \times \frac{\pi}{180} \text{ (mm/min)}
\]

- Automatic speed control for polar coordinate interpolation

If the velocity component of the rotary axis exceeds the maximum cutting feedrate in the polar coordinate interpolation mode, the speed is automatically controlled.
- Automatic override

If the velocity component of the rotary axis exceeds the permissible velocity (maximum cutting feedrate multiplied by the permission factor specified in parameter No. 5463), the feedrate is automatically overridden as indicated below.

\[
\text{Override} = \frac{\text{Permissible velocity}}{\text{Velocity component of rotary axis}} \times 100(\%)
\]

- Automatic speed clamp

If the velocity component of the rotary axis after automatic override still exceeds the maximum cutting feedrate, the speed of the rotary axis is automatically clamped. As a result, the velocity component of the rotary axis will not exceed the maximum cutting feedrate.

The automatic speed clamp function works only when the center of the tool is very close to the center of the rotary axis.

[Example]
G90 G00 X10.0 C0. ;
G12.1 ;
G01 C0.1 F1000 ;
X-10.0 ;
G13.1 ;

Automatic speed control for polar coordinate interpolation

Suppose that the maximum cutting feedrate of the rotary axis is 360 (3600 deg/min) and that the permission factor of automatic override for polar coordinate interpolation (parameter No. 5463) is 0 (90%). If the program indicated above is executed, the automatic override function starts working when the X coordinate becomes 2.273 (point A). The automatic speed clamp function starts working when the X coordinate becomes 0.524 (point B). The minimum value of automatic override for this example is 3%. The automatic speed clamp function continues working until the X coordinate becomes -0.524 (point C). Then, the automatic override function works until the X coordinate becomes -2.273 (point D). (The coordinates indicated above are the values in the Cartesian coordinate system.)

NOTE
1. While the automatic speed clamp function is working, the machine lock or interlock function may not be enabled immediately.
2. If a feed hold stop is made while the automatic speed clamp function is working, the automatic operation halt signal is output. However, the operation may not stop immediately.
3. The clamped speed may exceed the clamp value by a few percent.
Example

Sample program for polar coordinate interpolation in a Cartesian coordinate system consisting of the X-axis (a linear axis) and a hypothetical axis.

The X-axis is by diameter programming; the C-axis is by radius programming.

3.2 CONSTANT LEAD THREADING (G32)

Tapered screws and scroll threads in addition to equal lead straight threads can be cut by using a G32 command.

The spindle speed is read from the position coder on the spindle in real time and converted to a cutting feedrate for feed-per minute mode, which is used to move the tool.

**Fig. 3.2 (a) Thread types**

<table>
<thead>
<tr>
<th>Straight thread</th>
<th>Tapered screw</th>
<th>Scroll thread</th>
</tr>
</thead>
</table>

**Format**

G32IP_<F_>

- **IP**: End point
- **F**: Lead of the long axis
  - (always radius programming)

**Fig. 3.2 (b) Example of threading**
Explanation

In general, threading is repeated along the same tool path in rough cutting through finish cutting for a screw. Since threading starts when the position coder mounted on the spindle outputs a one-spindle-rotation signal, threading is started at a fixed point and the tool path on the workpiece is unchanged for repeated threading. Note that the spindle speed must remain constant from rough cutting through finish cutting. If not, incorrect thread lead will occur.

![Diagram of LZ and LX of a tapered thread](image)

In general, the lag of the servo system, etc. will produce somewhat incorrect leads at the starting and ending points of a thread cut. To compensate for this, a threading length somewhat longer than required should be specified. Table 3.2 (a) lists the ranges for specifying the thread lead.

<table>
<thead>
<tr>
<th>Table 3.2 (a) Ranges of lead sizes that can be specified</th>
</tr>
</thead>
<tbody>
<tr>
<td>Least command increment</td>
</tr>
<tr>
<td>Metric input</td>
</tr>
<tr>
<td>Inch input</td>
</tr>
</tbody>
</table>
Example

1. Straight threading

The following values are used in programming:
- Thread lead: 4mm
- $\delta_1$=3mm
- $\delta_2$=1.5mm
- Depth of cut: 1mm (cut twice)
- (Metric input, diameter programming)

G00 U-62.0 ;
G32 W-74.5 F4.0 ;
G00 U62.0 ;
W74.5 ;
U-64.0 ;
(For the second cut, cut 1mm more)
G32 W-74.5 ;
G00 U64.0 ;
W74.5 ;

2. Tapered threading

The following values are used in programming:
- Thread lead: 3.5mm in the direction of the Z axis
- $\delta_1$=2mm
- $\delta_2$=1mm
- Cutting depth in the X axis direction is 1mm (cut twice)
- (Metric input, diameter programming)

G00 X 12.0 Z 72.0 ;
G32 X 41.0 Z 29.0 F 3.5 ;
G00 X 50.0 ;
Z 72.0 ;
X 10.0 ;
(Cut 1mm more for the second cut)
G32 X 39.0 Z 29.0 ;
G00 X 50.0 ;
Z 72.0 ;
WARNING
1 Feedrate override is effective (fixed at 100%) during threading.
2 It is very dangerous to stop feeding the thread cutter without stopping the spindle. This will suddenly increase the cutting depth. Thus, the feed hold function is ineffective while threading. If the feed hold button is pressed during threading, the tool will stop after a block not specifying threading is executed as if the SINGLE BLOCK button were pushed. However, the feed hold lamp (SPL lamp) lights when the FEED HOLD button on the machine control panel is pushed. Then, when the tool stops, the lamp is turned off (Single Block stop status).
3 When the FEED HOLD button is pressed again in the first block after threading mode that does not specify threading (or the button has been held down), the tool stops immediately at the block that does not specify threading.
4 When threading is executed in the single block status, the tool stops after execution of the first block not specifying threading.
5 When the mode was changed from automatic operation to manual operation during threading, the tool stops at the first block not specifying threading as when the feed hold button is pushed as mentioned in Warning 3. However, when the mode is changed from one automatic operation mode to another, the tool stops after execution of the block not specifying threading as for the single block mode in Note 4.
6 When the previous block was a threading block, cutting will start immediately without waiting for detection of the one-spindle-rotation signal even if the present block is a threading block.
   G32Z _ F_;
   Z_; (A 1-turn signal is not detected before this block.)
   G32 ; (Regarded as threading block.)
   Z_F_; (One turn signal is also not detected.)
7 Because the constant surface speed control is effective during scroll thread or tapered screw cutting and the spindle speed changes, the correct thread lead may not be cut. Therefore, do not use the constant surface speed control during threading. Instead, use G97.
8 A movement block preceding the threading block must not specify chamfering or corner R.
9 A threading block must not specifying chamfering or corner R.
10 The spindle speed override function is disabled during threading. The spindle speed is fixed at 100%.
11 Thread cycle retract function is ineffective to G32.
3.3 VARIABLE LEAD THREADING (G34)

Specifying an increment or a decrement value for a lead per screw revolution enables variable lead threading to be performed.

![Variable lead screw](image)

**Fig. 3.3 (a) Variable lead screw**

**Format**

```
G34 IP_ F_ K_ ;
```

- **IP_**: End point
- **F_**: Lead in longitudinal axis direction at the start point
- **K_**: Increment and decrement of lead per spindle revolution

**Explanation**

Address other than K are the same as in straight/taper thread cutting with G32.

The K value depends on the increment system of the reference axis, as indicated in Table 3.3 (a).

If the specified K value exceeds the range indicated in Table 3.3 (a), if the maximum lead is exceeded after a change due to the K value, or if the lead value is negative, an alarm PS0313 will be issued.

**Table 3.3 (a) Range of valid K values**

<table>
<thead>
<tr>
<th>Increment system of reference axis</th>
<th>Metric input (mm/rev)</th>
<th>Inch input (inch/rev)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS-A</td>
<td>±0.001 to ±50.000</td>
<td>±0.00001 to ±50.0000</td>
</tr>
<tr>
<td>IS-B</td>
<td>±0.0001 to ±500.000</td>
<td>±0.000001 to ±50.00000</td>
</tr>
<tr>
<td>IS-C</td>
<td>±0.000001 to ±50.0000</td>
<td>±0.0000001 to ±5.000000</td>
</tr>
</tbody>
</table>

⚠️ **CAUTION**

The "thread cutting cycle retract" is not effective for G34.

**Example**

Lead at the start point: 8.0 mm
Lead increment: 0.3 mm/rev
```
G34 Z-72.0 F8.0 K0.3 ;
```
3.4 CONTINUOUS THREADING

Threading blocks can be programmed successively to eliminate a discontinuity due to a discontinuous movement in machining by adjacent blocks.

Explanation

Since the system is controlled in such a manner that the synchronism with the spindle does not deviate in the joint between blocks wherever possible, it is possible to perform special threading operation in which the lead and shape change midway.

![Fig. 3.4 (a) Continuous threading (Example of G32 in G code system A)]

Even when the same section is repeated for threading while changing the depth of cut, this system allows a correct machining without impairing the threads.
3.5 MULTIPLE THREADING

Using the Q address to specify an angle between the one-spindle-rotation signal and the start of threading shifts the threading start angle, making it possible to produce multiple-thread screws with ease.

![Multiple thread screws.](image)

**Format**

(Constant lead threading)

G32 IP_ F_ Q_;

- **IP**: End point
- **F_**: Lead in longitudinal direction

G32 IP_ Q_;

- **Q_**: Threading start angle

**Explanation**

- **Available threading commands**
  
  - G32: Constant lead threading
  - G34: Variable lead threading
  - G76: Multiple threading cycle
  - G92: Threading cycle

**Limitation**

- **Start angle**

  The start angle is not a continuous state (modal) value. It must be specified each time it is used. If a value is not specified, 0 is assumed.

- **Start angle increment**

  The start angle (Q) increment is 0.001 degrees. Note that no decimal point can be specified.

  **Example:**
  
  For a shift angle of 180 degrees, specify Q180000.
  
  Q180.000 cannot be specified, because it contains a decimal point.
- Specifiable start angle range

A start angle \((Q)\) of between 0 and 360000 (in 0.001-degree units) can be specified. If a value greater than 360000 (360 degrees) is specified, it is rounded down to 360000 (360 degrees).

- Multiple threading cycle (G76)

For the G76 multiple threading cycle command, always use the FS10/11 command format.

Example

| Program for producing double-threaded screws (with start angles of 0 and 180 degrees) |
| G00 X40.0 ; |
| G32 W-38.0 F4.0 Q0 ; |
| G00 X72.0 ; |
| W38.0 ; |
| X40.0 ; |
| G32 W-38.0 F4.0Q180000 ; |
| G00 X72.0 ; |
| W38.0 ; |
Chapter 4, "FUNCTIONS TO SIMPLIFY PROGRAMMING", consists of the following sections:

4.1 CANNED CYCLE (G90, G92, G94) .................................................. 38
4.2 MULTIPLE REPETITIVE CANNED CYCLE (G70-G76) ........... 59
4.3 CANNED CYCLE FOR DRILLING ................................................. 99
4.4 RIGID TAPPING ........................................................................ 115
4.5 CANNED GRINDING CYCLE
   (FOR GRINDING MACHINE) .................................................. 131
4.6 CHAMFERING AND CORNER R ................................................. 145
4.7 MIRROR IMAGE FOR DOUBLE TURRET (G68, G69) ...... 153
4.8 DIRECT DRAWING DIMENSION PROGRAMMING ............ 155
4.1 CANNED CYCLE (G90, G92, G94)

There are three canned cycles: the outer diameter/internal diameter cutting canned cycle (G90), the threading canned cycle (G92), and the end face turning canned cycle (G94).

**NOTE**

1. Explanatory figures in this section use the ZX plane as the selected plane, diameter programming for the X-axis, and radius programming for the Z-axis. When radius programming is used for the X-axis, change U/2 to U and X/2 to X.

2. A canned cycle can be performed on any plane (including parallel axes for plane definition). When G-code system A is used, however, U, V, and W cannot be set as a parallel axis.

3. The direction of the length means the direction of the first axis on the plane as follows:
   - ZX plane: Z-axis direction
   - YZ plane: Y-axis direction
   - XY plane: X-axis direction

4. The direction of the end face means the direction of the second axis on the plane as follows:
   - ZX plane: X-axis direction
   - YZ plane: Z-axis direction
   - XY plane: Y-axis direction
4.1.1 Outer Diameter/Internal Diameter Cutting Cycle (G90)

This cycle performs straight or taper cutting in the direction of the length.

4.1.1.1 Straight cutting cycle

Format

```
G90X(U)_Z(W)_F_;  
X_, Z_ : Coordinates of the cutting end point (point A' in the figure below) in the direction of the length  
U_, W_ : Travel distance to the cutting end point (point A' in the figure below) in the direction of the length  
F_ : Cutting feedrate
```

Explanation

- Operations

A straight cutting cycle performs four operations:

1) Operation 1 moves the tool from the start point (A) to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

2) Operation 2 moves the tool to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in cutting feed. (The tool is moved to the cutting end point (A') in the direction of the length.)

3) Operation 3 moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in cutting feed.

4) Operation 4 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

NOTE
In single block mode, operations 1, 2, 3 and 4 are performed by pressing the cycle start button once.

- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
4.1.1.2 Taper cutting cycle

**Format**

\[
\text{G90 X(U)_Z(W)_R_F_;}
\]

- **X, Z**: Coordinates of the cutting end point (point A' in the figure below) in the direction of the length
- **U, W**: Travel distance to the cutting end point (point A' in the figure below) in the direction of the length
- **R**: Taper amount (R in the figure below)
- **F**: Cutting feedrate

![Fig. 4.1.1 (b) Taper cutting cycle](image)

**Explanation**

The figure of a taper is determined by the coordinates of the cutting end point (A') in the direction of the length and the sign of the taper amount (address R). For the cycle in the figure above, a minus sign is added to the taper amount.

**NOTE**

The increment system of address R for specifying a taper depends on the increment system for the reference axis. Specify a radius value at R.

- **Operations**

A taper cutting cycle performs the same four operations as a straight cutting cycle. However, operation 1 moves the tool from the start point (A) to the position obtained by adding the taper amount to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse. Operations 2, 3, and 4 after operation 1 are the same as for a straight cutting cycle.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

**NOTE**
In single block mode, operations 1, 2, 3, and 4 are performed by pressing the cycle start button once.

---

- **Relationship between the sign of the taper amount and tool path**

  The tool path is determined according to the relationship between the sign of the taper amount (address R) and the cutting end point in the direction of the length in the absolute or incremental programming as follows.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. U &lt; 0, W &lt; 0, R &lt; 0</td>
<td>2. U &gt; 0, W &lt; 0, R &gt; 0</td>
</tr>
</tbody>
</table>

- **Canceling the mode**

  To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.1.2 Threading Cycle (G92)

4.1.2.1 Straight threading cycle

Format

```
G92 X(U)_Z(W)_F_Q_
```

- **X__,Z__**: Coordinates of the cutting end point (point A' in the figure below) in the direction of the length
- **U__,W__**: Travel distance to the cutting end point (point A' in the figure below) in the direction of the length
- **Q__**: Angle for shifting the threading start angle (Increment: 0.001 degrees, Valid setting range: 0 to 360 degrees)
- **F__**: Thread lead (L in the figure below)

![Diagram of threading cycle](image)

**Explanation**

The ranges of thread leads and restrictions related to the spindle speed are the same as for threading with G32.

- **Operations**

A straight threading cycle performs four operations:

1. Operation 1 moves the tool from the start point (A) to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

2. Operation 2 moves the tool to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in cutting feed. At this time, thread chamfering is performed.

3. Operation 3 moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in rapid traverse. (Retraction after chamfering)
(4) Operation 4 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)

⚠️ **CAUTION**

Notes on this threading are the same as in threading in G32. However, a stop by feed hold is as follows: Stop after completion of path 3 of threading cycle.

**NOTE**

In the single block mode, operations 1, 2, 3, and 4 are performed by pressing cycle start button once.

- **Canceling the mode**

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.

- **Acceleration/deceleration after interpolation for threading**

  Acceleration/deceleration after interpolation for threading is acceleration/deceleration of exponential interpolation type. By setting bit 5 (THLx) of parameter No. 1610, the same acceleration/deceleration as for cutting feed can be selected. (The settings of bit 0 (CTLx) of parameter No. 1610 are followed.) However, as a time constant and FL feedrate, the settings of parameter No. 1626 and No. 1627 for the threading cycle are used.

- **Time constant and FL feedrate for threading**

  The time constant for acceleration/deceleration after interpolation for threading specified in parameter No. 1626 and the FL feedrate specified in parameter No. 1627 are used.

- **Thread chamfering**

  Thread chamfering can be performed. A signal from the machine tool, initiates thread chamfering. The chamfering distance r is specified in a range from 0.1L to 12.7L in 0.1L increments by parameter No. 5130. (In the above expression, L is the thread lead.) A thread chamfering angle between 1 to 89 degrees can be specified in parameter No. 5131. When a value of 0 is specified in the parameter, an angle of 45 degrees is assumed.

  For thread chamfering, the same type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate as for threading are used.

**NOTE**

Common parameters for specifying the amount and angle of thread chamfering are used for this cycle and threading cycle with G76.
- Retraction after chamfering

The following table lists the feedrate, type of acceleration/deceleration after interpolation, and time constant of retraction after chamfering.

<table>
<thead>
<tr>
<th>Parameter CFR (No. 1611#0)</th>
<th>Parameter No. 1466</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Other than 0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and retraction feedrate specified in parameter No. 1466.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and rapid traverse rate specified in parameter No. 1420.</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).</td>
</tr>
</tbody>
</table>

By setting bit 4 (ROC) of parameter No. 1403 to 1, rapid traverse override can be disabled for the feedrate of retraction after chamfering.

**NOTE**

During retraction, the machine does not stop with an override of 0% for the cutting feedrate regardless of the setting of bit 4 (RF0) of parameter No. 1401.

- Shifting the start angle

Address Q can be used to shift the threading start angle. The start angle (Q) increment is 0.001 degrees and the valid setting range is between 0 and 360 degrees. No decimal point can be specified.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- **Feed hold in a threading cycle (threading cycle retract)**
  Feed hold may be applied during threading (operation 2). In this case, the tool immediately retracts with chamfering and returns to the start point on the second axis (X-axis), then the first axis (Z-axis) on the plane.

![Diagram of feed hold in threading cycle](image)

The chamfered angle is the same as that at the end point.

**CAUTION**
Another feed hold cannot be made during retreat.

- **Inch threading**
Inch threading specified with address E is not allowed.
4.1.2.2 Taper threading cycle

**Format**

```
G92 X(U)_Z(W)_R_F_Q_
```

- **X_**, **Z_**: Coordinates of the cutting end point (point A' in the figure below) in the direction of the length
- **U_**, **W_**: Travel distance to the cutting end point (point A' in the figure below) in the direction of the length
- **Q_**: Angle for shifting the threading start angle
  - Increment: 0.001 degrees,
  - Valid setting range: 0 to 360 degrees
- **R_**: Taper amount (R in the figure below)
- **F_**: Thread lead (L in the figure below)

(The chamfered angle in the left figure is 45 degrees or less because of the delay in the servo system.)

**Fig. 4.1.2 (d) Taper threading cycle**
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Explanation

The ranges of thread leads and restrictions related to the spindle speed are the same as for threading with G32.

The figure of a taper is determined by the coordinates of the cutting end point (A') in the direction of the length and the sign of the taper amount (address R). For the cycle in the figure above, a minus sign is added to the taper amount.

NOTE

The increment system of address R for specifying a taper depends on the increment system for the reference axis. Specify a radius value at R.

- Operations

A taper threading cycle performs the same four operations as a straight threading cycle.

However, operation 1 moves the tool from the start point (A) to the position obtained by adding the taper amount to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

Operations 2, 3, and 4 after operation 1 are the same as for a straight threading cycle.

⚠️ CAUTION

Notes on this threading are the same as in threading in G32. However, a stop by feed hold is as follows; Stop after completion of path 3 of threading cycle.

NOTE

In the single block mode, operations 1, 2, 3, and 4 are performed by pressing cycle start button once.
- Relationship between the sign of the taper amount and tool path

The tool path is determined according to the relationship between the sign of the taper amount (address R) and the cutting end point in the direction of the length in the absolute or incremental programming as follows.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. U &lt; 0, W &lt; 0, R &lt; 0</td>
<td>2. U &gt; 0, W &lt; 0, R &gt; 0</td>
</tr>
</tbody>
</table>

- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.

- Acceleration/deceleration after interpolation for threading
- Time constant and FL feedrate for threading
- Thread chamfering
- Retraction after chamfering
- Shifting the start angle
- Threading cycle retract
- Inch threading

See the pages on which a straight threading cycle is explained.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.1.3 End Face Turning Cycle (G94)

4.1.3.1 Face cutting cycle

Format

G94 X(U)_Z(W)_F_;  
X_,Z_ : Coordinates of the cutting end point (point A' in the figure below) in the direction of the end face 
U_,W_ : Travel distance to the cutting end point (point A' in the figure below) in the direction of the end face 
F_ : Cutting feedrate

Explanation

- Operations

A face cutting cycle performs four operations:

1. Operation 1 moves the tool from the start point (A) to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in rapid traverse.
2. Operation 2 moves the tool to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in cutting feed. (The tool is moved to the cutting end point (A') in the direction of the end face.)
3. Operation 3 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in cutting feed.
4. Operation 4 moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)

NOTE

In single block mode, operations 1, 2, 3, and 4 are performed by pressing the cycle start button once.
- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.

### 4.1.3.2 Taper cutting cycle

#### Format

<table>
<thead>
<tr>
<th>G94 X(U)_Z(W)<em>R_F</em>;</th>
</tr>
</thead>
<tbody>
<tr>
<td>X_ : Coordinates of the cutting end point (point A' in the figure below) in the direction of the end face</td>
</tr>
<tr>
<td>Z_ : Travel distance to the cutting end point (point A’ in the figure below) in the direction of the end face</td>
</tr>
<tr>
<td>U_ : Taper amount (R in the figure below)</td>
</tr>
<tr>
<td>F_ : Cutting feedrate</td>
</tr>
</tbody>
</table>

#### Explanation

The figure of a taper is determined by the coordinates of the cutting end point (A’) in the direction of the end face and the sign of the taper amount (address R). For the cycle in the figure above, a minus sign is added to the taper amount.

#### NOTE

The increment system of address R for specifying a taper depends on the increment system for the reference axis. Specify a radius value at R.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- Operations

A taper cutting cycle performs the same four operations as a face cutting cycle. However, operation 1 moves the tool from the start point (A) to the position obtained by adding the taper amount to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in rapid traverse. Operations 2, 3, and 4 after operation 1 are the same as for a face cutting cycle.

**NOTE**

In single block mode, operations 1, 2, 3, and 4 are performed by pressing the cycle start button once.

- Relationship between the sign of the taper amount and tool path

The tool path is determined according to the relationship between the sign of the taper amount (address R) and the cutting end point in the direction of the end face in the absolute or incremental programming as follows.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. U &lt; 0, W &lt; 0, R &lt; 0</td>
<td>2. U &gt; 0, W &lt; 0, R &lt; 0</td>
</tr>
<tr>
<td>3. U &lt; 0, W &lt; 0, R &gt; 0</td>
<td>4. U &gt; 0, W &lt; 0, R &gt; 0</td>
</tr>
</tbody>
</table>

- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
4.1.4 How to Use Canned Cycles (G90, G92, G94)

An appropriate canned cycle is selected according to the shape of the material and the shape of the product.

- Straight cutting cycle (G90)

- Taper cutting cycle (G90)
- Face cutting cycle (G94)

- Face taper cutting cycle (G94)
4.1.5 Canned Cycle and Tool Nose Radius Compensation

When tool nose radius compensation is applied, the tool nose center path and offset direction are as shown below. At the start point of a cycle, the offset vector is canceled. Offset start-up is performed for the movement from the start point of the cycle. The offset vector is temporarily canceled again at the return to the cycle start point and offset is applied again according to the next move command. The offset direction is determined depending of the cutting pattern regardless of the G41 or G42 mode.

Outer diameter/internal diameter cutting cycle (G90)

End face cutting cycle (G94)

Threading cycle (G92)

Tool nose radius compensation cannot be applied.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Differences between this CNC and the Series 0i-C

**NOTE**

This CNC is the same as the Series 0i-C in the offset direction, but differs from the series in the tool nose radius center path.
- For this CNC
  Cycle operations of a canned cycle are replaced with G00 or G01. In the first block to move the tool from the start point, start-up is performed. In the last block to return the tool to the start point, offset is canceled.
- For the Series 0i-C
  This series differs from this CNC in operations in the block to move the tool from the start point and the last block to return it to the start point. For details, refer to "Series 0i-C Operator's Manual."

How compensation is applied for the Series 0i-C

4.1.6 Restrictions on Canned Cycles

Limitation
- Modal

Since data items X (U), Z (W), and R in a canned cycle are modal values common to G90, G92, and G94. For this reason, if a new X (U), Z (W), or R value is not specified, the previously specified value is effective.

Thus, when the travel distance along the Z-axis does not vary as shown in the program example below, a canned cycle can be repeated only by specifying the travel distance along the X-axis.

![Example Diagram]

The cycle in the above figure is executed by the following program:

```
N030 G90 U-8.0 W-66.0 F0.4;
N031 U-16.0;
N032 U-24.0;
N033 U-32.0;
```

The modal values common to canned cycles are cleared when a one-shot G code other than G04 is specified.

Since the canned cycle mode is not canceled by specifying a one-shot G code, a canned cycle can be performed again by specifying modal values. If no modal values are specified, no cycle operations are performed.

When G04 is specified, G04 is executed and no canned cycle is performed.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- Block in which no move command is specified
In a block in which no move command is specified in the canned cycle mode, a canned cycle is also performed. For example, a block containing only EOB or a block in which none of the M, S, and T codes, and move commands are specified is of this type of block. When an M, S, or T code is specified in the canned cycle mode, the corresponding M, S, or T function is executed together with the canned cycle. If this is inconvenient, specify a group 01 G code (G00 or G01) other than G90, G92, or G94 to cancel the canned cycle mode, and specify an M, S, or T code, as in the program example below. After the corresponding M, S, or T function has been executed, specify the canned cycle again.

Example

| N003 T0101; |
| : |
| : |
| N010 G90 X20.0 Z10.0 F0.2; |
| N011 G00 T0202; ← Cancels the canned cycle mode. |
| N012 G90 X20.5 Z10.0; |

- Plane selection command
Specify a plane selection command (G17, G18, or G19) before setting a canned cycle or specify it in the block in which the first canned cycle is specified. If a plane selection command is specified in the canned cycle mode, the command is executed, but the modal values common to canned cycles are cleared. If an axis which is not on the selected plane is specified, alarm PS0330 is issued.

- Parallel axis
When G code system A is used, U, V, and W cannot be specified as a parallel axis.

- Reset
If a reset operation is performed during execution of a canned cycle when any of the following states for holding a modal G code of group 01 is set, the modal G code of group 01 is replaced with the G01 mode:

- Reset state (bit 6 (CLR) of parameter No. 3402 = 0)
- Cleared state (bit 6 (CLR) of parameter No. 3402 = 1) and state where the modal G code of group 01 is held at reset time (bit 1 (C01) of parameter No. 3406 = 1)

Example of operation
If a reset is made during execution of a canned cycle (X0 block) and the X20.Z1. command is executed, linear interpolation (G01) is performed instead of the canned cycle.
4.2 MULTIPLE REPETITIVE CANNED CYCLE (G70-G76)

The multiple repetitive canned cycle is canned cycles to make CNC programming easy. For instance, the data of the finish work shape describes the tool path for rough machining. And also, a canned cycles for the threading is available.

NOTE
1 Explanatory figures in this section use the ZX plane as the selected plane, diameter programming for the X-axis, and radius programming for the Z-axis. When radius programming is used for the X-axis, change U/2 to U and X/2 to X.
2 A multiple repetitive canned cycle can be performed on any plane (including parallel axes for plane definition). When G-code system A is used, however, U, V, and W cannot be set as a parallel axis.
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

4.2.1 Stock Removal in Turning (G71)

There are two types of stock removals in turning: Type I and II.

Format

ZpXp plane
G71 U(Δd) R(e) ;
G71 P(ns) Q(nf) U(Δu) W(Δw) F(f ) S(s ) T(t ) ;
N (ns) ; } The move commands for the target figure from A
... to A' to B are specified in the blocks with
N (nf) ; sequence numbers ns to nf.

YpZp plane
G71 W(Δd) R(e) ;
G71 P(ns) Q(nf) V(Δw) W(Δu) F(f ) S(s ) T(t ) ;
N (ns) ;

XpYp plane
G71 V(Δd) R(e) ;
G71 P(ns) Q(nf) U(Δw) V(Δu) F(f ) S(s ) T(t ) ;
N (ns) ;
...
N (nf) ;

Δd : Depth of cut
The cutting direction depends on the direction AA'.
This designation is modal and is not changed until the
other value is designated. Also this value can be
specified by the parameter (No. 5132), and the
parameter is changed by the program command.

e : Escaping amount
This designation is modal and is not changed until the
other value is designated. Also this value can be
specified by the parameter (No. 5133), and the
parameter is changed by the program command.

ns : Sequence number of the first block for the program of
finishing shape.

nf : Sequence number of the last block for the program of
finishing shape.

Δu : Distance of the finishing allowance in the direction of
the second axis on the plane (X-axis for the ZX plane)

Δw : Distance of the finishing allowance in the direction of
the first axis on the plane (Z-axis for the ZX plane)

f,s,t : Any F, S, or T function contained in blocks ns to nf in
the cycle is ignored, and the F, S, or T function in this
G71 block is effective.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

<td>Required</td>
</tr>
</tbody>
</table>

**Explanation**

**Operations**

When a target figure passing through A, A', and B in this order is given by a program, the specified area is removed by \(\Delta d\) (depth of cut), with the finishing allowance specified by \(\Delta u/2\) and \(\Delta w\) left. After the last cutting is performed in the direction of the second axis on the plane (X-axis for the ZX plane), rough cutting is performed as finishing along the target figure. After rough cutting as finishing, the block next to the sequence block specified at Q is executed.

**Fig. 4.2.1 (a) Cutting path in stock removal in turning (type I)**
NOTE
1 While both $\Delta d$ and $\Delta u$ are specified by the same address, the meanings of them are determined by the presence of addresses P and Q.
2 The cycle machining is performed by G71 command with P and Q specification.
3 F, S, and T functions which are specified in the move command between points A and B are ineffective and those specified in G71 block or the previous block are effective. M and second auxiliary functions are treated in the same way as F, S, and T functions.
4 When the constant surface speed control function is enabled (bit 0 (SSC) of parameter No. 8133 is set to 1), the G96 or G97 command specified in the move command between points A and B is ignored. If you want to enable the G96 or G97 command, specify the command in the G71 or previous block.

- Target figure Patterns

The following four cutting patterns are considered. All of these cutting cycles cut the workpiece with moving the tool in parallel to the first axis on the plane (Z-axis for the ZX plane). At this time, the signs of the finishing allowances of $\Delta u$ and $\Delta w$ are as follows:

![Four target figure patterns](image-url)
4. FUNCTIONS TO SIMPLIFY

PROGRAMMING

Limitation

(1) For U(+), a figure for which a position higher than the cycle start point is specified cannot be machined.
   For U(-), a figure for which a position lower than the cycle start point is specified cannot be machined.

(2) For type I, the figure must show monotone increase or decrease along the first and second axes on the plane.

(3) For type II, the figure must show monotone increase or decrease along the first axis on the plane.

- Start block

In the start block in the program for a target figure (block with sequence number ns in which the path between A and A’ is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.

When G00 is specified, positioning is performed along A-A’. When G01 is specified, linear interpolation is performed with cutting feed along A-A’.

In this start block, also select type I or II.

- Check functions

During cycle operation, whether the target figure shows monotone increase or decrease is always checked.

NOTE

When tool nose radius compensation is applied, the target figure to which compensation is applied is checked.

The following checks can also be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
<tr>
<td>Checks the target figure before cycle operation. (Also checks that a block with the sequence number specified at address Q is contained.)</td>
<td>Enabled when bit 2 (FCK) of parameter No. 5104 is set to 1.</td>
</tr>
</tbody>
</table>
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

- Types I and II
Selection of type I or II

For G71, there are types I and II. When the target figure has pockets, be sure to use type II. Escaping operation after rough cutting in the direction of the first axis on the plane (Z-axis for the ZX plane) differs between types I and II. With type I, the tool escapes to the direction of 45 degrees. With type II, the tool cuts the workpiece along the target figure. When the target figure has no pockets, determine the desired escaping operation and select type I or II.

Selecting type I or II

In the start block for the target figure (sequence number ns), select type I or II.

1) When type I is selected
Specify the second axis on the plane (X-axis for the ZX plane). Do not specify the first axis on the plane (Z-axis for the ZX plane).

2) When type II is selected
Specify the second axis on the plane (X-axis for the ZX plane) and first axis on the plane (Z-axis for the ZX plane). When you want to use type II without moving the tool along the first axis on the plane (Z-axis for the ZX plane), specify the incremental programming with travel distance 0 (W0 for the ZX plane).

- Type I

(1) In the block with sequence number ns, only the second axis on the plane (X-axis (U-axis) for the ZX plane) must be specified.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZX plane</td>
</tr>
<tr>
<td>G71 V10.0 R5.0 ;</td>
</tr>
<tr>
<td>G71 P100 Q200...;</td>
</tr>
<tr>
<td><strong>N100 X(U)_</strong> ; (Specifies only the second axis on the plane.)</td>
</tr>
<tr>
<td>;</td>
</tr>
<tr>
<td>;</td>
</tr>
<tr>
<td>N200............;</td>
</tr>
</tbody>
</table>
(2) The figure along path A'-B must show monotone increase or decrease in the directions of both axes forming the plane (Z- and X-axes for the ZX plane). It must not have any pocket as shown in the figure below.

![Fig. 4.2.1 (c) Figure which does not show monotone increase or decrease (type I)](image)

⚠️ CAUTION
If a figure does not show monotone change along the first or second axis on the plane, alarm PS0064 or PS0329 is issued. If the movement does not show monotone change, but is very small, and it can be determined that the movement is not dangerous, however, the permissible amount can be specified in parameters Nos. 5145 and 5146 to specify that the alarm is not issued in this case.

(3) The tool escapes to the direction of 45 degrees in cutting feed after rough cutting.

![Fig. 4.2.1 (d) Cutting in the direction of 45 degrees (type I)](image)

(4) Immediately after the last cutting, rough cutting is performed as finishing along the target figure. Bit 1 (RF1) of parameter No. 5105 can be set to 1 so that rough cutting as finishing is not performed.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- Type II

When a target figure passing through A, A', and B in this order is given by the program for a target figure as shown in the figure, the specified area is removed by \( \Delta d \) (depth of cut), with the finishing allowance specified by \( \Delta u/2 \) and \( \Delta w \) left. Type II differs from type I in cutting the workpiece along the figure after rough cutting in the direction of the first axis on the plane (Z-axis for the ZX plane). After the last cutting, the tool returns to the start point specified in G71 and rough cutting is performed as finishing along the target figure, with the finishing allowance specified by \( \Delta u/2 \) and \( \Delta w \) left.

Type II differs from type I in the following points:
1. In the block with sequence number ns, the two axes forming the plane (X-axis (U-axis) and Z-axis (W-axis) for the ZX plane) must be specified. When you want to use type II without moving the tool along the Z-axis on the ZX plane in the first block, specify W0.

Example

<table>
<thead>
<tr>
<th>ZX plane</th>
</tr>
</thead>
<tbody>
<tr>
<td>G71 V10.0 R5.0;</td>
</tr>
<tr>
<td>G71 P100 Q200......;</td>
</tr>
<tr>
<td>N100 X(U) Z(W) ; (Specifies the two axes forming the plane.)</td>
</tr>
<tr>
<td>: :</td>
</tr>
<tr>
<td>: :</td>
</tr>
<tr>
<td>N200.............;</td>
</tr>
</tbody>
</table>
(2) The figure need not show monotone increase or decrease in the direction of the second axis on the plane (X-axis for the ZX plane) and it may have concaves (pockets).

The figure must show monotone change in the direction of the first axis on the plane (Z-axis for the ZX plane), however. The following figure cannot be machined.

⚠️ CAUTION
For a figure along which the tool moves backward along the first axis on the plane during cutting operation (including a vertex in an arc command), the cutting tool may contact the workpiece. For this reason, for a figure which does not show monotone change, alarm PS0064 or PS0329 is issued. If the movement does not show monotone change, but is very small, and it can be determined that the movement is not dangerous, however, the permissible amount can be specified in parameter No. 5145 to specify that the alarm is not issued in this case.

The first cut portion need not be vertical. Any figure is permitted if monotone change is shown in the direction of the first axis on the plane (Z-axis for the ZX plane).
4. FUNCTIONS TO SIMPLIFY

PROGRAMMING

Fig. 4.2.1 (h) Figure which can be machined (type II)

(3) After turning, the tool cuts the workpiece along its figure and escapes in cutting feed.

Fig. 4.2.1 (i) Cutting along the workpiece figure (type II)

The escaping amount after cutting (e) can be specified at address R or set in parameter No. 5133.
When moving from the bottom, however, the tool escapes to the direction of 45 degrees.

Fig. 4.2.1 (j) Escaping from the bottom to the direction of 45 degrees

(4) When a position parallel to the first axis on the plane (Z-axis for the ZX plane) is specified in a block in the program for the target figure, it is assumed to be at the bottom of a pocket.
(5) After all rough cutting terminates along the first axis on the plane (Z-axis for the ZX plane), the tool temporarily returns to the cycle start point. At this time, when there is a position whose height equals to that at the start point, the tool passes through the point in the position obtained by adding depth of cut \( \Delta d \) to the position of the figure and returns to the start point. Then, rough cutting is performed as finishing along the target figure. At this time, the tool passes through the point in the obtained position (to which depth of cut \( \Delta d \) is added) when returning to the start point. Bit 2 (RF2) of parameter No. 5105 can be set to 1 so that rough cutting as finishing is not performed.

![Escaping operation after rough cutting as finishing](image)

**Fig. 4.2.1 (k) Escaping operation when the tool returns to the start point (type II)**

(6) Order and path for rough cutting of pockets

Rough cutting is performed in the following order.

(a) When the figure shows monotone decrease along the first axis on the plane (Z-axis for the ZX plane)

![Rough cutting order in the case of monotone decrease](image)

**Fig. 4.2.1 (l) Rough cutting order in the case of monotone decrease (type II)**
(b) When the figure shows monotone increase along the first axis on the plane (Z-axis for the ZX plane)

Rough cutting is performed in the order <1>, <2>, and <3> from the leftmost pocket.

Fig. 4.2.1 (m) Rough cutting order in the case of monotone increase (type II)

The path in rough cutting is as shown below.

Fig. 4.2.1 (n) Cutting path for multiple pockets (type II)

The following figure shows how the tool moves after rough cutting for a pocket in detail.

Fig. 4.2.1 (o) Details of motion after cutting for a pocket (type II)

Cuts the workpiece at the cutting feedrate and escapes to the direction of 45 degrees. (Operation 19)
Then, moves to the height of point D in rapid traverse. (Operation 20)
Then, moves to the position the amount of g before point D.
(Operation 21)
Finally, moves to point D in cutting feed.
The clearance g to the cutting feed start position is set in parameter No. 5134.
For the last pocket, after cutting the bottom, the tool escapes to the
direction of 45 degrees and returns to the start point in rapid traverse.
(Operations 34 and 35)

⚠️ CAUTION
1. This CNC differs from the Series 0i-C in cutting of a pocket.
   The tool first cuts the nearest pocket to the start point. After cutting of the pocket terminates, the
tool moves to the nearest but one pocket and starts cutting.
2. When the figure has a pocket, generally specify a value of 0 for \( \Delta w \) (finishing allowance). Otherwise, the tool may dig into the wall on one side.

- Tool nose radius compensation

When using tool nose radius compensation, specify a tool nose radius
compensation command (G41, G42) before a multiple repetitive
canned cycle command (G70, G71, G72, G73) and specify the cancel
command (G40) outside the blocks (from the block specified with P to
the block specified with Q) specifying a target finishing figure.
If a tool nose radius compensation command (G40, G41, or G42) is
specified in the G70, G71, G72, or G73 command, alarm PS0325 is
issued.
When this cycle is specified in the tool nose radius compensation
mode, offset is temporarily canceled during movement to the start
point. Start-up is performed in the first block. Offset is temporarily
canceled again at the return to the cycle start point after termination of
cycle operation. Start-up is performed again according to the next
move command. This operation is shown in the figure below.
This cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.

**NOTE**
To perform pocketing in the tool nose radius compensation mode, specify the linear block A-A' outside the workpiece and specify the figure of an actual pocket. This prevents a pocket from being dug.
- Movement to the previous turning start point

Movement to the turning start point is performed with two operations. (Operations 1 and 2 in the figure below.) As movement to the present turning start point, operation 1 temporarily moves the tool to the previous turning start point, then operation 2 moves the tool to the present turning start point.

Operation 1 moves the tool in cutting feed. Operation 2 moves the tool according to the mode (G00 or G01) specified in the start block in the geometry program.

Bit 0 (ASU) of parameter No. 5107 can be set to 1 so that operation 1 moves the tool in rapid traverse.

For a type I command

- Rapid traverse can be selected.
- According to the mode in the start block.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.2.2 Stock Removal in Facing (G72)

This cycle is the same as G71 except that cutting is performed by an operation parallel to the second axis on the plane (X-axis for the ZX plane).

- Target figure
- Tool path
- $\Delta u/2$
- $45^\circ$
- $\Delta w$
- $+X$
- $+Z$
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

Explanation
- Operations

When a target figure passing through A, A’, and B in this order is given by a program, the specified area is removed by Δd (depth of cut), with the finishing allowance specified by Δu/2 and Δw left.

NOTE
1 While both Δd and Δu are specified by the same address, the meanings of them are determined by the presence of addresses P and Q.
2 The cycle machining is performed by G72 command with P and Q specification.
3 F, S, and T functions which are specified in the move command between points A and B are ineffective and those specified in G72 block or the previous block are effective. M and second auxiliary functions are treated in the same way as F, S, and T functions.
4 When the constant surface speed control function is enabled (bit 0 (SSC) of parameter No. 8133 is set to 1), the G96 or G97 command specified in the move command between points A and B is ignored. If you want to enable the G96 or G97 command, specify the command in the G71 or previous block.

- Target figure
Patterns

The following four cutting patterns are considered. All of these cutting cycles cut the workpiece with moving the tool in parallel to the second axis on the plane (X-axis for the ZX plane). At this time, the signs of the finishing allowances of Δu and Δw are as follows:

Fig. 4.2.2 (r) Signs of the values specified at U and W in stock removal in facing
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

Limitation

(1) For \( W(+) \), a figure for which a position higher than the cycle start point is specified cannot be machined.
For \( W(-) \), a figure for which a position lower than the cycle start point is specified cannot be machined.

(2) For type I, the figure must show monotone increase or decrease along the first and second axes on the plane.

(3) For type II, the figure must show monotone increase or decrease along the second axis on the plane.

- Start block

In the start block in the program for a target figure (block with sequence number \( ns \) in which the path between A and A' is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.
When G00 is specified, positioning is performed along A-A'. When G01 is specified, linear interpolation is performed with cutting feed along A-A'.
In this start block, also select type I or II.

- Check functions

During cycle operation, whether the target figure shows monotone increase or decrease is always checked.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
<tr>
<td>Checks the target figure before cycle operation. (Also checks that a block with the sequence number specified at address Q is contained.)</td>
<td>Enabled when bit 2 (FCK) of parameter No. 5104 is set to 1.</td>
</tr>
</tbody>
</table>

NOTE
When tool nose radius compensation is applied, the target figure to which compensation is applied is checked.

The following checks can also be made.

- Types I and II
Selection of type I or II

For G72, there are types I and II.
When the target figure has pockets, be sure to use type II.
Escaping operation after rough cutting in the direction of the second axis on the plane (X-axis for the ZX plane) differs between types I and II. With type I, the tool escapes to the direction of 45 degrees. With type II, the tool cuts the workpiece along the target figure. When the target figure has no pockets, determine the desired escaping operation and select type I or II.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Selecting type I or II

In the start block for the target figure (sequence number ns), select type I or II.

(1) When type I is selected
Specify the first axis on the plane (Z-axis for the ZX plane). Do not specify the second axis on the plane (X-axis for the ZX plane).

(2) When type II is selected
Specify the second axis on the plane (X-axis for the ZX plane) and first axis on the plane (Z-axis for the ZX plane).
When you want to use type II without moving the tool along the second axis on the plane (X-axis for the ZX plane), specify the incremental programming with travel distance 0 (U0 for the ZX plane).

- Type I

G72 differs from G71 in the following points:

(1) G72 cuts the workpiece with moving the tool in parallel with the second axis on the plane (X-axis on the ZX plane).

(2) In the start block in the program for a target figure (block with sequence number ns), only the first axis on the plane (Z-axis (W-axis) for the ZX plane) must be specified.

- Type II

G72 differs from G71 in the following points:

(1) G72 cuts the workpiece with moving the tool in parallel with the second axis on the plane (X-axis on the ZX plane).

(2) The figure need not show monotone increase or decrease in the direction of the first axis on the plane (Z-axis for the ZX plane) and it may have concaves (pockets). The figure must show monotone change in the direction of the second axis on the plane (X-axis for the ZX plane), however.

(3) When a position parallel to the second axis on the plane (X-axis for the ZX plane) is specified in a block in the program for the target figure, it is assumed to be at the bottom of a pocket.

(4) After all rough cutting terminates along the second axis on the plane (X-axis for the ZX plane), the tool temporarily returns to the start point. Then, rough cutting as finishing is performed.

- Tool nose radius compensation

See the pages on which G71 is explained.

- Movement to the previous turning start point

See the pages on which G71 is explained.
4.2.3 Pattern Repeating (G73)

This function permits cutting a fixed pattern repeatedly, with a pattern being displaced bit by bit. By this cutting cycle, it is possible to efficiently cut work whose rough shape has already been made by a rough machining, forging or casting method, etc.

| ... |
| N (nf) ; |

\( \Delta i \) : Distance of escape in the direction of the second axis on the plane (X-axis for the ZX plane)

This designation is modal and is not changed until the other value is designated. Also this value can be specified by the parameter No. 5135, and the parameter is changed by the program command.

\( \Delta k \) : Distance of escape in the direction of the first axis on the plane (Z-axis for the ZX plane)

This designation is modal and is not changed until the other value is designated. Also this value can be specified by the parameter No. 5136, and the parameter is changed by the program command.

\( d \) : The number of division

This value is the same as the repetitive count for rough cutting. This designation is modal and is not changed until the other value is designated. Also, this value can be specified by the parameter No. 5137, and the parameter is changed by the program command.

\( n_s \) : Sequence number of the first block for the program of finishing shape.

\( n_f \) : Sequence number of the last block for the program of finishing shape.

\( \Delta u \) : Distance of the finishing allowance in the direction of the second axis on the plane (X-axis for the ZX plane)

\( \Delta w \) : Distance of the finishing allowance in the direction of the first axis on the plane (Z-axis for the ZX plane)

f, s, t : Any F, S, and T function contained in the blocks between sequence number "ns" and "nf" are ignored, and the F, S, and T functions in this G73 block are effective.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

<table>
<thead>
<tr>

<td>Required</td>
</tr>
<tr>
<td>Δu</td>
<td>Depends on the increment system for the reference axis.</td>
<td>Depends on diameter/radius programming for the second axis on the plane.</td>
<td>Required</td>
</tr>
<tr>
<td>Δw</td>
<td>Depends on the increment system for the reference axis.</td>
<td>Depends on diameter/radius programming for the first axis on the plane.</td>
<td>Required</td>
</tr>
</tbody>
</table>

NOTE

Decimal point input is allowed with d. However, a value rounded off to an integer is used as the number of division, regardless of the setting of bit 0 (DPI) of parameter No. 3401. When an integer is input, the input integer is used as the number of division.

Fig. 4.2.3 (s) Cutting path in pattern repeating
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Explanation
- Operations

When a target figure passing through A, A', and B in this order is given by a program, rough cutting is performed the specified number of times, with the finishing allowance specified by $\Delta u/2$ and $\Delta w$ left.

**NOTE**

1. While the values $\Delta i$ and $\Delta k$, or $\Delta u$ and $\Delta w$ are specified by the same address respectively, the meanings of them are determined by the presence of addresses P and Q.
2. The cycle machining is performed by G73 command with P and Q specification.
3. After cycle operation terminates, the tool returns to point A.
4. F, S, and T functions which are specified in the move command between points A and B are ineffective and those specified in G73 block or the previous block are effective. M and second auxiliary functions are treated in the same way as F, S, and T functions.

- Target figure
  Patterns

As in the case of G71, there are four target figure patterns. Be careful about signs of $\Delta u$, $\Delta w$, $\Delta i$, and $\Delta k$ when programming this cycle.

- Start block

In the start block in the program for the target figure (block with sequence number ns in which the path between A and A' is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.

When G00 is specified, positioning is performed along A-A'. When G01 is specified, linear interpolation is performed with cutting feed along A-A'.

- Check function

The following check can be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
</tbody>
</table>

- Tool nose radius compensation

Like G71, this cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.
4.2.4 Finishing Cycle (G70)

After rough cutting by G71, G72 or G73, the following command permits finishing.

Format

G70 P(ns) Q(nf) ;
ns : Sequence number of the first block for the program of finishing shape.
nf : Sequence number of the last block for the program of finishing shape.

Explanation

- Operations

The blocks with sequence numbers ns to nf in the program for a target figure are executed for finishing. The F, S, T, M, and second auxiliary functions specified in the G71, G72, or G73 block are ignored and the F, S, T, M, and second auxiliary functions specified in the blocks with sequence numbers ns to nf are effective.

When cycle operation terminates, the tool is returned to the start point in rapid traverse and the next G70 cycle block is read.

- Target figure

Check function

The following check can be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
</tbody>
</table>

- Storing P and Q blocks

When rough cutting is executed by G71, G72, or G73, up to three memory addresses of P and Q blocks are stored. By this, the blocks indicated by P and Q are immediately found at execution of G70 without searching memory from the beginning for them. After some G71, G72, and G73 rough cutting cycles are executed, finishing cycles can be performed by G70 at a time. At this time, for the fourth and subsequent rough cutting cycles, the cycle time is longer because memory is searched for P and Q blocks.
Example

G71 P100 Q200 ...;
N100 ...;
...;
N200 ...;
G71 P300 Q400 ...;
N300 ...;
...;
N400 ...;
...;
G70 P100 Q200 ; (Executed without a search for the first to third cycles)
G70 P300 Q400 ; (Executed after a search for the fourth and subsequent cycles)

NOTE

The memory addresses of P and Q blocks stored during rough cutting cycles by G71, G72, and G73 are erased after execution of G70. All stored memory addresses of P and Q blocks are also erased by a reset.

- Return to the cycle start point

In a finishing cycle, after the tool cuts the workpiece to the end point of the target figure, it returns to the cycle start point in rapid traverse.

NOTE

The tool returns to the cycle start point always in the nonlinear positioning mode regardless of the setting of bit 1 (LRP) of parameter No. 1401. Before executing a finishing cycle for a target figure with a pocket cut by G71 or G72, check that the tool does not interfere with the workpiece when returning from the end point of the target figure to the cycle start point.

- Tool nose radius compensation

Like G71, this cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.
Example

Stock removal in facing (G72)

N020   G70 P014 Q019 ;
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.2.5 End Face Peck Drilling Cycle (G74)

This cycle enables chip breaking in outer diameter cutting. If the second axis on the plane (X-axis (U-axis) for the ZX plane) and address P are omitted, operation is performed only along the first axis on the plane (Z-axis for the ZX plane), that is, a peck drilling cycle is performed.

Format

<td>Radius programming</td>
<td>Not required</td>
</tr>
<tr>
<td>\Delta d</td>
<td>Depends on the increment system for the reference axis.</td>
<td>Radius programming</td>
<td>NOTE</td>
</tr>
</tbody>
</table>

NOTE

Normally, specify a positive value for \Delta d. When X (U) and \Delta i are omitted, specify a value with the sign indicating the direction in which the tool is to escape.
**Explanation**

**- Operations**

A cycle operation of cutting by \( \Delta k \) and return by \( e \) is repeated. When cutting reaches point C, the tool escapes by \( \Delta d \). Then, the tool returns in rapid traverse, moves to the direction of point B by \( \Delta i \), and performs cutting again.

**NOTE**

1. While both \( e \) and \( \Delta d \) are specified by the same address, the meanings of them are determined by specifying the X, Y, or Z axis. When the axis is specified, \( \Delta d \) is used.
2. The cycle machining is performed by G74 command with specifying the axis.

**- Tool nose radius compensation**

Tool nose radius compensation cannot be applied.
This cycle is equivalent to G74 except that the second axis on the plane (X-axis for the ZX plane) changes places with the first axis on the plane (Z-axis for the ZX plane). This cycle enables chip breaking in end facing. It also enables grooving during outer diameter cutting and cutting off (when the Z-axis (W-axis) and Q are omitted for the first axis on the plane).

**Format**

```
G75R (e) ;
G75X(U)_ Z(W)_ P(\Delta i) Q(\Delta k) R(\Delta d) F (f) ;
```

- **e**: Return amount
  - This designation is modal and is not changed until the other value is designated. Also this value can be specified by the parameter No. 5139, and the parameter is changed by the program command.

- **X_, Z_**: Coordinate of the second axis on the plane (X-axis for the ZX plane) at point B and coordinate of the first axis on the plane (Z-axis for the ZX plane) at point C

- **U_, W_**: Travel distance along the second axis on the plane (U for the ZX plane) from point A to B and travel distance along the first axis on the plane (W for the ZX plane) from point A to C
  - (When G code system A is used. In other cases, X_, Z_ is used for specification.)

- **\Delta i**: Depth of cut in the direction of the second axis on the plane (X-axis for the ZX plane)

- **\Delta k**: Travel distance in the direction of the first axis on the plane (Z-axis for the ZX plane)

- **\Delta d**: Relief amount of the tool at the cutting bottom

- **f**: Feedrate

**Unit Diameter/radius programming Sign Decimal point input**

</tr>
</tbody>
</table>

**NOTE**

Normally, specify a positive value for \( \Delta d \). When Z (W) and \( \Delta k \) are omitted, specify a value with the sign indicating the direction in which the tool is to escape.
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

**Explanation**

- **Operations**

A cycle operation of cutting by $\Delta i$ and return by $e$ is repeated. When cutting reaches point B, the tool escapes by $\Delta d$. Then, the tool returns in rapid traverse, moves to the direction of point C by $\Delta k$, and performs cutting again.

Both G74 and G75 are used for grooving and drilling, and permit the tool to relief automatically. Four symmetrical patterns are considered, respectively.

- **Tool nose radius compensation**

  Tool nose radius compensation cannot be applied.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.2.7 Multiple Threading Cycle (G76)

This threading cycle performs one edge cutting by the constant amount of cut.

Format

G76 P(m) (r) (a) Q(\Delta d_{\text{min}}) R(d) ;
G76 X(U)_ Z(W)_ R(i) P(k) Q(\Delta d) F(L) ;

- m : Repetitive count in finishing (1 to 99)
  This value can be specified by the parameter No. 5142, and the parameter is changed by the program command.
- r : Chamfering amount (0 to 99)
  When the thread lead is expressed by L, the value of L can be set from 0.0L to 9.9L in 0.1L increment (2-digit number). This value can be specified by the parameter No. 5130, and the parameter is changed by the program command.
- a : Angle of tool nose
  One of six kinds of angle, 80°, 60°, 55°, 30°, 29°, and 0°, can be selected, and specified by 2-digit number. This value can be specified by the parameter No. 5143, and the parameter is changed by the program command.
- m, r, and a are specified by address P at the same time.
  (Example) When m=2, r=1.2L, a=60°, specify as shown below (L is lead of thread).

P 02 12 60
a r m

- \Delta d_{\text{min}} : Minimum cutting depth
  When the cutting depth of one cycle operation becomes smaller than this limit, the cutting depth is clamped at this value. This value can be specified by parameter No. 5140, and the parameter is changed by the program command.
- d : Finishing allowance
  This value can be specified by parameter No. 5141, and the parameter is changed by the program command.
- X_, Z_ : Coordinates of the cutting end point (point D in the figure) in the direction of the length
- U_, W_ : Travel distance to the cutting end point (point D in the figure) in the direction of the length
  (When G code system A is used. In other cases, X_,Z_ is used for specification.)
- i : Taper amount
  If i = 0, ordinary straight threading can be made.
- k : Height of thread
- \Delta d : Depth of cut in 1st cut
- L : Lead of thread

Fig. 4.2.7 (c) Cutting path in multiple threading cycle

Fig. 4.2.7 (d) Detail of cutting
4. FUNCTIONS TO SIMPLIFY

- Repetitive count in finishing

The last finishing cycle (cycle in which the finishing allowance is removed by cutting) is repeated.

Explanation
- Operations

This cycle performs threading so that the length of the lead only between C and D is made as specified in the F code. In other sections, the tool moves in rapid traverse.

The time constant for acceleration/deceleration after interpolation and FL feedrate for thread chamfering and the feedrate for retraction after chamfering are the same as for thread chamfering with G92 (canned cycle).

NOTE
1. The meanings of the data specified by address P, Q, and R determined by the presence of X (U) and Z (W).
2. The cycle machining is performed by G76 command with X (U) and Z (W) specification.
3. The values specified at addresses P, Q, and R are modal and are not changed until another value is specified.

CAUTION
Notes on threading are the same as those on G32 threading. For feed hold in a threading cycle, however, see "Feed hold in a threading cycle" described below.
- Relationship between the sign of the taper amount and tool path

The signs of incremental dimensions for the cycle shown in Fig. 4.2.7 (c) are as follows:
Cutting end point in the direction of the length for U and W:
Minus (determined according to the directions of paths A-C and C-D)
Taper amount (i):
Minus (determined according to the direction of path A-C)
Height of thread (k):
Plus (always specified with a plus sign)
Depth of cut in the first cut (∆d):
Plus (always specified with a plus sign)
The four patterns shown in the table below are considered corresponding to the sign of each address. A female thread can also be machined.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. U &lt; 0, W &lt; 0, i &lt; 0</td>
<td>2. U &gt; 0, W &lt; 0, i &gt; 0</td>
</tr>
</tbody>
</table>

- Acceleration/deceleration after interpolation for threading

Acceleration/deceleration after interpolation for threading is acceleration/deceleration of exponential interpolation type. By setting bit 5 (THLx) of parameter No. 1610, the same acceleration/deceleration as for cutting feed can be selected. (The settings of bit 0 (CTLx) of parameter No. 1610 are followed.) However, as a time constant and FL feedrate, the settings of parameter No. 1626 and No. 1627 for the threading cycle are used.

- 93 -
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- **Time constant and FL feedrate for threading**
  The time constant for acceleration/deceleration after interpolation for threading specified in parameter No. 1626 and the FL feedrate specified in parameter No. 1627 are used.

- **Thread chamfering**
  Thread chamfering can be performed in this threading cycle. A signal from the machine tool initiates thread chamfering.
  The maximum amount of thread chamfering (r) that can be specified in the command is 99 (9.9L). The amount can be specified in a range from 0.1L to 12.7L in 0.1L increments in parameter No. 5130.
  A thread chamfering angle between 1 to 89 degrees can be specified in parameter No. 5131. When a value of 0 is specified in the parameter, an angle of 45 degrees is assumed.
  For thread chamfering, the same type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate as for threading are used.

**NOTE**
Common parameters for specifying the amount and angle of thread chamfering are used for this cycle and G92 threading cycle.

- **Retraction after chamfering**
  The following table lists the feedrate, type of acceleration/deceleration after interpolation, and time constant of retraction after chamfering.

<table>
<thead>
<tr>
<th>Parameter CFR (No. 1611#0)</th>
<th>Parameter No. 1466</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Other than 0</td>
<td></td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and retraction feedrate specified in parameter No. 1466.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and rapid traverse rate specified in parameter No. 1420.</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).</td>
</tr>
</tbody>
</table>

By setting bit 4 (ROC) of parameter No. 1403 to 1, rapid traverse override can be disabled for the feedrate of retraction after chamfering.
- Shifting the start angle

The threading start angle cannot be shifted.

- Feed hold in a threading cycle (threading cycle retract)

Feed hold may be applied during threading in a combined threading cycle (G76). In this case, the tool quickly retracts in the same way as for the last chamfering in a threading cycle and returns to the start point in the current cycle (position where the workpiece is cut by $\Delta dn$).

When cycle start is triggered, the multiple threading cycle resumes.

The angle of chamfering during retraction is the same as that of chamfering at the end point.

- Inch threading

Inch threading specified with address E is not allowed.

- Tool nose radius compensation

Tool nose radius compensation cannot be applied.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Example

G80 X80.0 Z130.0;
G76 P011060 Q100 R200;
G76 X60.64 Z25.0 P3680 Q1800 F6.0;

G80 X80.0 Z130.0;
G76 P011060 Q100 R200;
G76 X60.64 Z25.0 P3680 Q1800 F6.0;
4.2.8 Restrictions on Multiple Repetitive Canned Cycle (G70-G76)

Programmed commands

- Program memory

Programs using G70, G71, G72, or G73 must be stored in the program memory. The use of the mode in which programs stored in the program memory are called for operation enables these programs to be executed in other than the MEM mode. Programs using G74, G75, or G76 need not be stored in the program memory.

- Blocks in which data related to a multiple repetitive canned cycle is specified

The addresses P, Q, X, Z, U, W, and R should be specified correctly for each block.

In a block in which G70, G71, G72, or G73 is specified, the following functions cannot be specified:

- Custom macro calls
  (simple call, modal call, and subprogram call)

- Blocks in which data related to a target figure is specified

In the block which is specified by address P of a G71, G72 or G73, G00 or G01 code in group 01 should be commanded. If it is not commanded, alarm PS0065 is generated.

In blocks with sequence numbers between those specified at P and Q in G70, G71, G72, and G73, the following commands can be specified:

- Dwell (G04)
- G00, G01, G02, and G03
  When a circular interpolation command (G02, G03) is used, there must be no radius difference between the start point and end point of the arc. If there is a radius difference, the target finishing figure may not be recognized correctly, resulting in a cutting error such as excessive cutting.
- Custom macro branch and repeat command
  The branch destination must be between the sequence numbers specified at P and Q, however. High-speed branch specified by bits 1 and 4 of parameter No. 6000 is invalid. No custom macro call (simple, modal, or subprogram call) cannot be specified.
- Direct drawing dimension programming command and chamfering and corner R command
  Direct drawing dimension programming and chamfering and corner R require multiple blocks to be specified. The block with the last sequence number specified at Q must not be an intermediate block of these specified blocks.

When G70, G71, G72, or G73 is executed, the sequence number specified by address P and Q should not be specified twice or more in the same program.

When #1 = 2500 is executed using a custom macro, 2500.000 is assigned to #1. In such a case, P#1 is equivalent to P2500.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Relation with other functions

- **Manual intervention**
  While a multiple repetitive canned cycle (G70 to G76) is being executed, it is possible to stop the cycle and to perform manual intervention. The setting of manual absolute on or off is effective for manual operation.

- **Interruption type macro**
  Any interruption type macro program cannot be executed during execution of a multiple repetitive canned cycle.

- **Program restart and tool retract and recover**
  These functions cannot be executed in a block in a multiple repetitive canned cycle.

- **Axis name and second auxiliary functions**
  Even if address U, V, or W is used as an axis name or second auxiliary function, data specified at address U, V, or W in a G71 to G73 block is assumed to be that for the multiple repetitive canned cycle.

- **Tool nose radius compensation**
  When using tool nose radius compensation, specify a tool nose radius compensation command (G41, G42) before a multiple repetitive canned cycle command (G70, G71, G72, G73) and specify the cancel command (G40) outside the blocks (from the block specified with P to the block specified with Q) specifying a target finishing figure.
4.3  CANNED CYCLE FOR DRILLING

Canned cycles for drilling make it easier for the programmer to create programs. With a canned cycle, a frequently-used machining operation can be specified in a single block with a G function; without canned cycles, more than one block is required. In addition, the use of canned cycles can shorten the program to save memory.

Table 4.3 (a) lists canned cycles for drilling.

**Explanation**

The canned cycle for drilling consists of the following six operation sequences.

- Operation 1 ......... Positioning of X (Z) and C axis
- Operation 2 ......... Rapid traverse up to point R level
- Operation 3 ......... Hole machining
- Operation 4 ......... Operation at the bottom of a hole
- Operation 5 ......... Retraction to point R level
- Operation 6 ......... Rapid traverse up to the initial level
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

- Positioning axis and drilling axis

The C-axis and X- or Z-axis are used as positioning axes. The X- or Z-axis, which is not used as a positioning axis, is used as a drilling axis. A drilling G code specifies positioning axes and a drilling axis as shown below.

Although canned cycles include tapping and boring cycles as well as drilling cycles, in this chapter, only the term drilling will be used to refer to operations implemented with canned cycles.

<table>
<thead>
<tr>
<th>G code</th>
<th>Positioning axis</th>
<th>Drilling axis</th>
</tr>
</thead>
<tbody>
<tr>
<td>G83, G84, G85</td>
<td>X axis, C axis</td>
<td>Z axis</td>
</tr>
<tr>
<td>G87, G88, G89</td>
<td>Z axis, C axis</td>
<td>X axis</td>
</tr>
</tbody>
</table>

G83 and G87, G84 and G88, and G85 and G89 have the same function respectively except for axes specified as positioning axes and a drilling axis.

- Drilling mode

G83 to G85/G87 to G89 are modal G codes and remain in effect until canceled. When in effect, the current state is the drilling mode.

Once drilling data is specified in the drilling mode, the data is retained until modified or canceled.

Specify all necessary drilling data at the beginning of canned cycles; when canned cycles are being performed, specify data modifications only.

The feedrate specified at F is retained also after the drilling cycle is canceled. When Q data is required, it must be specified in each block. Once specified, the M code used for C-axis clamp/unclamp functions as a modal code. It is canceled by specifying G80.
- **Return point level (G98, G99)**

In G code system A, the tool returns to the initial level from the bottom of a hole. In G code system B or C, specifying G98 returns the tool to the initial level from the bottom of a hole and specifying G99 returns the tool to the point R level from the bottom of a hole.

The following illustrates how the tool moves when G98 or G99 is specified. Generally, G99 is used for the first drilling operation and G98 is used for the last drilling operation.

The initial level does not change even when drilling is performed in the G99 mode.

<table>
<thead>
<tr>
<th>G98 (Return to initial level)</th>
<th>G99 (Return to point R level)</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Diagram" /></td>
<td><img src="image2.png" alt="Diagram" /></td>
</tr>
</tbody>
</table>

- **Number of repeats**

To repeat drilling for equally-spaced holes, specify the number of repeats in K. K is effective only within the block where it is specified.

Specify the first hole position in incremental programming. If it is specified in absolute programming, drilling is repeated at the same position.

<table>
<thead>
<tr>
<th>Number of repeats K</th>
<th>The maximum command value = 9999</th>
</tr>
</thead>
</table>

When K0 is specified, drilling data is just stored without drilling being performed.

**NOTE**

For K, specify an integer of 0 or 1 to 9999.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- M code used for C-axis clamp/unclamp
When an M code specified in parameter No. 5110 for C-axis clamp/unclamp is coded in a program, the following operations occur.
- The CNC issues the M code for C-axis clamp after the tool is positioned and while the tool is being fed in rapid traverse to the point-R level.
- The CNC issues the M code for C-axis unclamp (the M code for C-axis clamp +1) after the tool retracts to the point-R level.
- After the CNC issues the M code for C-axis unclamp, the tool dwells for the time specified in parameter No. 5111.

- Cancel
To cancel a canned cycle, use G80 or a group 01 G code.

Group 01 G codes (Example)
G00: Positioning (rapid traverse)
G01: Linear interpolation
G02: Circular interpolation (CW)
G03: Circular interpolation (CCW)

- Symbols in figures
Subsequent subsections explain the individual canned cycles. Figures in these explanations use the following symbols:

<table>
<thead>
<tr>

<td>Issuing the M code for C-axis unclamp</td>
</tr>
</tbody>
</table>

⚠️ CAUTION
1. In each canned cycle, addresses R, Z, and X are handled as follows:
   - R_: Always handled as a radius.
   - Z_ or X_: Depends on diameter/radius programming.
2. For the B or C G-code system, G90 or G91 can be used to select an incremental or absolute programming for hole position data (X, C or Z, C), the distance from point R to the bottom of the hole (Z or X), and the distance from the initial level to the point R level (R).
4.3.1 Front Drilling Cycle (G83)/Side Drilling Cycle (G87)

The peck drilling cycle or high-speed peck drilling cycle is used depending on the setting in RTR, bit 2 of parameter No. 5101. If depth of cut for each drilling is not specified, the normal drilling cycle is used.

- High-speed peck drilling cycle (G83, G87) (parameter RTR (No. 5101#2) = 0)

This cycle performs high-speed peck drilling. The drill repeats the cycle of drilling at the cutting feedrate and retracting the specified retraction distance intermittently to the bottom of a hole. The drill draws cutting chips out of the hole when it retracts.

**Format**

| G83 X(U)_ C(H)_ Z(W)_ R_ P_ Q_ F_ K_ M_ ; |

4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

4.3.2 Front Tapping Cycle (G84) / Side Tapping Cycle (G88)

This cycle performs tapping. In this tapping cycle, when the bottom of the hole has been reached, the spindle is rotated in the reverse direction.

Format

G84 X(U)_ C(H)_ Z(W)_ R_ P_ Q_ F_ K_ M_ ;
or
G88 Z(W)_ C(H)_ X(U)_ R_ P_ Q_ F_ K_ M_ ;

X_ C_ or Z_ C_ : Hole position data
Z_ or X_  : The distance from point R to the bottom of the hole
R_ : The distance from the initial level to point R level
P_ : Dwell time at the bottom of a hole
Q_ : Depth of cut for each cutting feed (Bit 6 (PCT) of parameter No. 5104 = "1")
F_ : Cutting feedrate
K_ : Number of repeats (When it is needed.)
M_ : M code for C-axis clamp (when it is needed.)

G84 or G88 (G98 mode) | G84 or G88 (G99 mode)
---|---

Explanation

Tapping is performed by rotating the spindle clockwise. When the bottom of the hole has been reached, the spindle is rotated in the reverse direction for retraction. This operation creates threads. Feedrate overrides are ignored during tapping. A feed hold does not stop the machine until the return operation is completed.
NOTE
Bit 3 (M5T) of parameter No. 5105 specifies whether the spindle stop command (M05) is issued before the direction in which the spindle rotates is specified with M03 or M04. For details, refer to the operator's manual created by the machine tool builder.

- Q command

After setting bit 6 (PCT) of parameter No. 5104 to 1, add address Q to the ordinary tapping cycle command format and specify the depth of cut for each tapping.

In the peck tapping cycle, the tool is retracted to point R for each tapping. In the high-speed peck tapping cycle, the tool is retracted by the retraction distance specified for parameter No. 5213 in advance. Which operation is to be performed can be selected by setting bit 5 (PCP) of parameter No. 5200.

Operation

First, ordinary tapping cycle operation is explained as basic operation.

Before specifying a tapping cycle, rotate the spindle using a miscellaneous function.

1. When a command to position the tool to a hole position, positioning is performed.
2. When point R is specified, positioning to point R is performed.
3. Tapping is performed to the bottom of the hole in cutting feed.
4. When a dwell time (P) is specified, the tool dwells.
5. Miscellaneous function M05 (spindle stop) is output and the machine enters the FIN wait state.
6. When FIN is returned, miscellaneous function M04 (reverse spindle rotation) is output and the machine enters the FIN wait state.
7. When FIN is returned, the tap is removed until point R is reached in cutting feed.
8. When a dwell time (P) is specified, the tool dwells.
9. Miscellaneous function M05 (spindle stop) is output and the machine enters the FIN wait state.
10. When FIN is returned, miscellaneous function M03 (forward spindle rotation) is output, and the machine enters the FIN wait state.
11. When FIN is returned, the tool returns to the initial point in rapid traverse when return to the initial level is specified.

When the repetitive count is specified, operation is repeated from step 1.
Peck tapping cycle

When bit 6 (PCT) of parameter No. 5104 is set 1 and bit 5 (PCP) of parameter No. 5200 is set to 1, the peck tapping cycle is used. Step 3 of the tapping cycle operation described above changes as follows:

3-1. The tool cuts the workpiece by the depth of cut q specified by address Q.
3-2. Miscellaneous function M05 (spindle stop) is output, and the machine enters the FIN wait state.
3-3. When FIN is returned, miscellaneous function M04 (reverse spindle rotation) is output, and the machine enters the FIN wait state.
3-4. When FIN is returned, the tool is retracted to point R in cutting feed.
3-5. Miscellaneous function M05 (spindle stop) is output, and the machine enters the FIN wait state.
3-6. When FIN is returned, miscellaneous function M03 (forward spindle rotation) is output, and the machine enters the FIN wait state.
3-7. When FIN is returned, the tool moves to the position the clearance d (parameter No. 5213) apart from the previous cutting point in cutting feed (approach).
3-1. The tool cuts the workpiece by the clearance d (parameter No. 5213) + depth of cut q (specified by address Q).

Tapping is performed to the bottom of the hole by repeating the above steps.
When a dwell time (P) is specified, the tool dwells only when it reaches at the bottom of the hole and reaches point R last.

![Diagram showing the sequence of events in the tapping cycle.](image)

**High-speed peck tapping cycle**

When bit 6 (PCT) of parameter No. 5104 is set 1 and bit 5 (PCP) of parameter No. 5200 is set to 0, the high-speed peck tapping cycle is used.

Step 3 of the tapping cycle operation described above changes as follows:

3-1. The tool cuts the workpiece by the depth of cut q specified by address Q.
3-2. Miscellaneous function M05 (spindle stop) is output, and the machine enters the FIN wait state.
3-3. When FIN is returned, miscellaneous function M04 (reverse spindle rotation) is output, and the machine enters the FIN wait state.
3-4. When FIN is returned, the tool is retracted by the retraction distance d specified by parameter No. 5213 in cutting feed.
3-5. Miscellaneous function M05 (spindle stop) is output, and the machine enters the FIN wait state.
3-6. When FIN is returned, miscellaneous function M03 (forward spindle rotation) is output, and the machine enters the FIN wait state.
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

3-1. When FIN is returned, the tool cuts the workpiece by the retraction distance \( d \) (parameter No. 5213) + depth of cut \( q \) (specified by address Q).

Tapping is performed to the bottom of the hole by repeating the above steps.
When a dwell time (P) is specified, the tool dwells only when it reaches at the bottom of the hole and reaches point R.

Notes

1. The depth of cut specified by address Q is stored as a modal value until the canned cycle mode is canceled.
   In both examples 1 and 2 below, address Q is not specified in the N20 block, but the peck tapping cycle is performed because the value specified by address Q is valid as a modal value. If this operation is not suitable, specify G80 to cancel the canned cycle mode as shown in N15 in example 3 or specify Q0 in the tapping block as shown in N20 in example 4.

Example 1
N10 G84 X100. Y150. Z-100. Q20. ;
N20 X150. Y200 ; ← The peck tapping cycle is also performed in this block.
N30 G80 ;
Example 2
N10 G83 X100. Y150. Z-100. Q20 ;
N20 G84 Z-100. ; ← The peck tapping cycle is also performed in this block.
N30 G80 ;

Example 3
N10 G83 X100. Y150. Z-100. Q20 ;
N15 G80 ; ← The canned cycle mode is canceled.
N20 G84 Z-100. ;
N30 G80 ;

Example 4
N10 G83 X100. Y150. Z-100. Q20 ;
N20 G84 Z-100. Q0 ; ← Q0 is added.
N30 G80 ;

2. The unit for the reference axis that is set by parameter No. 1031, not the unit for the drilling axis is used as the unit of Q. Any sign is ignored.

3. Specify a radius value at address Q even when a diameter axis is used.

4. Perform operation in the peck tapping cycle within point R. That is, set a value which does not exceed point R for d (parameter No. 5213).

Example

M51 ; Setting C-axis index mode ON
M3 S2000 ; Rotating the drill
G00 X50.0 C0.0 ; Positioning the drill along the X- and C-axes
G84 Z-40.0 R-5.0 P500 F5.0 M31 ; Drilling hole 1
C90.0 M31 ; Drilling hole 2
C180.0 M31 ; Drilling hole 3
C270.0 M31 ; Drilling hole 4
G80 M05 ; Canceling the drilling cycle and stopping drill rotation
M50 ; Setting C-axis index mode off
4.3.3 Front Boring Cycle (G85) / Side Boring Cycle (G89)

This cycle is used to bore a hole.

**Format**

```
G85 X(U)_ C(H)_ Z(W)_ R_ P_ F_ K_ M_ ;
```

or

```
G89 Z(W)_ C(H)_ X(U)_ R_ P_ F_ K_ M_ ;
```

- **X** or **Z** : Hole position data
- **Z** or **X** : The distance from point R to the bottom of the hole
- **R** : The distance from the initial level to point R level
- **P** : Dwell time at the bottom of a hole
- **F** : Cutting feedrate
- **K** : Number of repeats (When it is needed.)
- **M** : M code for C-axis clamp (When it is needed.)

**G85 or G89 (G98 mode)**

- `M_α`: M code for C-axis clamp
- `M (α + 1)`: M code for C-axis unclamp
- **P1**: Dwell specified in the program
- **P2**: Dwell specified in parameter No. 5111

**G85 or G89 (G99 mode)**

- `M_α`: M code for C-axis clamp
- `M (α + 1)`: M code for C-axis unclamp
- **P1**: Dwell specified in the program
- **P2**: Dwell specified in parameter No. 5111

**Explanation**

After positioning, rapid traverse is performed to point R. Drilling is performed from point R to point Z. After the tool reaches point Z, it returns to point R at a feedrate twice the cutting feedrate.

**Example**

```
M51 ;  Setting C-axis index mode ON
M3 S2000 ;  Rotating the drill
G00 X50.0 C0.0 ;  Positioning the drill along the X- and C-axes
G85 Z-40.0 R-5.0 P500 F5.0 M31 ;  Drilling hole 1
C90.0 M31 ;  Drilling hole 2
C180.0 M31 ;  Drilling hole 3
C270.0 M31 ;  Drilling hole 4
G80 M05 ;  Canceling the drilling cycle and stopping drill rotation
M50 ;  Setting C-axis index mode off
```
4.3.4 Canned Cycle for Drilling Cancel (G80)

G80 cancels canned cycle for drilling.

Format

```
G80 ;
```

Explanation

Canned cycle for drilling is canceled to perform normal operation. Point R and point Z are cleared. Other drilling data is also canceled (cleared).

Example

```
M51 ;                      Setting C-axis index mode ON
M3 S2000 ;                 Rotating the drill
G00 X50.0 C0.0 ;          Positioning the drill along the X- and C-axes.
G80 Z-40.0 R-5.0 P500 F5.0 M31 ; Drilling hole 1
C90.0 M31 ;               Drilling hole 2
C180.0 M31 ;              Drilling hole 3
C270.0 M31 ;              Drilling hole 4
G80 M05 ;                 Canceling the drilling cycle and stopping drill rotation
M50 ;                     Setting C-axis index mode off
```
4.3.5 Precautions to be Taken by Operator

- Reset and emergency stop

Even when the controller is stopped by resetting or emergency stop in the course of drilling cycle, the drilling mode and drilling data are saved; with this mind, therefore, restart operation.

- Single block

When drilling cycle is performed with a single block, the operation stops at the end points of operations 1, 2, 6 in Fig. 4.3 (a). Consequently, it follows that operation is started up 3 times to drill one hole. The operation stops at the end points of operations 1, 2 with the feed hold lamp ON. If there is a remaining repetitive count at the end of operation 6, the operation is stopped by feed hold. If there is no remaining repetitive count, the operation is stopped in the single block stop state.

- Feed hold

When "Feed Hold" is applied between operations 3 and 5 by G84/G88, the feed hold lamp lights up immediately if the feed hold is applied again to operation 6.

- Override

During operation with G84 and G88, the feedrate override is 100%.
4.4 RIGID TAPPING

Front face tapping cycles (G84) and side face tapping cycles (G88) can be performed either in conventional mode or rigid mode.

In conventional mode, the spindle is rotated or stopped, in synchronization with the motion along the tapping axis according to miscellaneous functions M03 (spindle CW rotation), M04 (spindle CCW rotation), and M05 (spindle stop).

In rigid mode, the spindle motor is controlled in the same way as a control motor, by the application of compensation to both motion along the tapping axis and that of the spindle.

For rigid tapping, each turn of the spindle corresponds to a certain amount of feed (screw lead) along the spindle axis. This also applies to acceleration/deceleration. This means that rigid tapping does not demand the use of float tappers as in the case of conventional tapping, thus enabling high-speed, high-precision tapping.

When multispindle control is enabled (bit 3 (MSP) of parameter No. 8133 is set to 1), the second spindle can be used for rigid tapping.
Controlling the spindle motor in the same way as a servo motor in rigid mode enables high-speed tapping.

**Format**

<table>
<thead>
<tr>
<th>G84 or G88 (G98 mode)</th>

In side face rigid tapping (G88), the plane first axis is used as the drilling axis and the other axes are used as positioning axes.
A G code cannot discriminate between front face tapping cycle and side face tapping cycle using Series 10/11 format commands. The drilling axis is determined by plane selection (G17/G18/G19). Specify the plane selection that becomes equivalent to front face tapping cycle or side face tapping cycle as appropriate. (When FXY (bit 0 of parameter No. 5101) is 0, the Z-axis is used as the drilling axis. When FXY is 1, plane selection is as follows.)

<table>
<thead>
<tr>
<th>Plane selection</th>
<th>Drilling axis</th>
</tr>
</thead>
<tbody>
<tr>
<td>G17 Xp-Yp plane</td>
<td>Zp</td>
</tr>
<tr>
<td>G18 Zp-Xp plane</td>
<td>Yp</td>
</tr>

<td>Xp</td>
</tr>
</tbody>
</table>

Xp: X axis or its parallel axis  
Yp: Y axis or its parallel axis  
Zp: Z axis or its parallel axis

**Explanation**

Once positioning for the X-axis (G84) or Z-axis (G88) has been completed, the spindle is moved, by rapid traverse, to point R. Tapping is performed from point R to point Z, after which the spindle stops and observes a dwell time. Then, the spindle starts reverse rotation, retracts to point R, stops rotating, then moves to the initial level by rapid traverse.

During tapping, the feedrate override and spindle override are assumed to be 100%. For retraction (operation 5), however, a fixed override of up to 2000% can be applied by setting parameters DOV (No. 5200#4), OVU (No.5201#3), and No. 5211.

- **Rigid mode**

Rigid mode can be specified by applying any of the following methods:

- Specifying M29S***** before a tapping block
- Specifying M29S***** within a tapping block
- Handling G84 or G88 as a G code for rigid tapping (Set parameter G84 (No. 5200#0) to 1.)

- **Thread lead**

In feed per minute mode, the feedrate divided by the spindle speed is equal to the thread lead. In feed per rotation mode, the feedrate is equal to the thread lead.

- **Series 10/11 format command**

When bit 1 (FCV) of parameter No. 0001 is set to 1, rigid tapping can be executed with G84.2. The same operation as with G84 is performed. The command format for the repetitive count is L, however.

- **Acceleration/deceleration after interpolation**

Linear or bell-shaped acceleration/deceleration can be applied. Details are given later.
- **Look-ahead acceleration/deceleration before interpolation**
  
  Look-ahead acceleration/deceleration before interpolation is invalid.

- **Override**
  
  Various types of override functions are invalid. The following override functions can be enabled by setting corresponding parameters:
  
  - Extraction override
  - Override signal

- **Dry run**
  
  Dry run can be executed also in G84 (G88). When dry run is executed at the feedrate for the drilling axis in G84 (G88), tapping is performed according to the feedrate. Note that the spindle speed becomes faster at a higher dry run feedrate.

- **Machine lock**
  
  Machine lock can be executed also in G84 (G88). When G84 (G88) is executed in the machine lock state, the tool does not move along the drilling axis. Therefore, the spindle does not also rotate.

- **Reset**
  
  When a reset is performed during rigid tapping, the rigid tapping mode is canceled and the spindle motor enters the normal mode. Note that the G84 (G88) mode is not canceled in this case when bit 6 (CLR) of parameter No. 3402 is set.

- **Interlock**
  
  Interlock can also be applied in G84 (G88).

- **Feed hold and single block**
  
  When parameter FHD (No. 5200#6) is set to 0, feed hold and single block are invalid in the G84 (G88) mode. When this bit is set to 1, they are valid.

- **Manual feed**
  
  For rigid tapping by manual handle feed, see the section "Rigid Tapping by Manual Handle."
  
  With other manual operations, rigid tapping cannot be performed.

- **Backlash compensation**
  
  In the rigid tapping mode, backlash compensation is applied to compensate the lost motion when the spindle rotates clockwise or counterclockwise. Set the amount of backlash in parameters Nos. 5321 to 5324.
  
  Along the drilling axis, backlash compensation has been applied.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- C-axis clamp, C-axis unclamp

It is possible to specify an M code for mechanically fixing or releasing the C-axis during rigid tapping. Adding an M code for clamp to the G84 (G88) block outputs both M codes. Descriptions of timing are provided later.

An M code for clamp is set in parameter No. 5110. An M code for unclamp is assumed as follows depending on the setting of parameter No. 5110.

<table>
<thead>
<tr>
<th>Parameter No.5110</th>
<th>0</th>
<th>Non-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>No M codes are output.</td>
<td>The setting of parameter No.5110 + 1 is assumed.</td>
<td></td>
</tr>
</tbody>
</table>

Limitation
- Axis switching

Before the drilling axis can be changed, the canned cycle must be canceled. If the drilling axis is changed in rigid mode, alarm PS0206 is issued.

- S commands

When a value exceeding the maximum rotation speed for the gear being used is specified, alarm PS0200 is issued. If such a command that the number of pulses of 8 msec is 32768 or more on the detection unit level or the number of pulses of 8 msec is 32768 or more for a serial spindle is specified, alarm PS0202 is issued.

<Example>

For a built-in motor equipped with a detector having a resolution of 4095 pulses per rotation, the maximum spindle speed during rigid tapping is as follows (in the case of 8 msec):

\[
(4095 \times 1000 \div 8 \times 60) \div 4095 = 7500 \text{ (min}^{-1})
\]

For a serial spindle

\[
(32767 \times 1000 \div 8 \times 60) \div 4095 = 60012 \text{(min}^{-1}) \]

[Note: Ideal value]

When rigid tapping is canceled, the S value used for rigid tapping is cleared (as if S0 is specified).

- F commands

Specifying a value larger than the upper limit for cutting feed will cause alarm PS0201 to be issued.

- Unit of F command

<table>
<thead>
<tr>
<th>Metric input</th>
<th>Inch input</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>G98 1mm/min</td>
<td>0.01inch/min</td>
<td>Decimal point programming allowed</td>
</tr>
<tr>
<td>G99 0.01mm/rev</td>
<td>0.0001inch/rev</td>
<td>Decimal point programming allowed</td>
</tr>
</tbody>
</table>

- M29

If an S command and axis movement are specified between M29 and G84, alarm PS0203 is issued. If M29 is specified in a tapping cycle, alarm PS0204 is issued.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- Rigid tapping command M code

The M code used to specify the rigid tapping mode is set in parameter No. 5210.

- P

Specify P in a block that performs drilling. If P is specified in a non-drilling block, it is not stored as modal data.

- Cancel

Do not specify a G code of the 01 group (G00 to G03) and G84 in a single block. Otherwise, G84 will be canceled.

- Tool offset

In the canned cycle mode, tool offsets are ignored.

- Program restart

A program cannot be restarted during rigid tapping.

- R

The value of R must be specified in a block which performs drilling. If the value is specified in a block which does not perform drilling, it is not stored as modal data.

- Subprogram call

In the canned cycle mode, specify the subprogram call command M98P_ in an independent block.

Example

Tapping axis feedrate: 1000 mm/min
Spindle speed: 1000 min⁻¹
Screw lead: 1.0 mm

G00 X100.0 ; ............................................................... Positioning
M29 S1000 ; ........................ Command for specifying rigid mode
G84 Z-100.0 R-20.0 F1.0 ; ...........................................Rigid tapping
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.4.2 Peck Rigid Tapping Cycle (G84 or G88)

Tapping a deep hole in rigid tapping mode may be difficult due to chips sticking to the tool or increased cutting resistance. In such cases, the peck rigid tapping cycle is useful.

In this cycle, cutting is performed several times until the bottom of the hole is reached. Two peck tapping cycles are available: High-speed peck tapping cycle and standard peck tapping cycle. These cycles are selected using the bit 5 (PCP) of parameter No. 5200.

**Format**

When rigid tapping is specified with G84 (G88) if bit 5 (PCP) of parameter No. 5200 = 0, high-speed peck rigid tapping is assumed.

<table>
<thead>
<tr>
<th>G84 X(U)_ C(H)_ Z(W)_ R_ P_ Q_ F_ K_ M_ ;</th>
<th>G84 or G88(G98 mode)</th>
<th>G84 or G88(G99 mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td>or</td>
<td></td>
<td></td>
</tr>
<tr>
<td>G88 Z(W)_ C(H)_ X(U)_ R_ P_ Q_ F_ K_ M_ ;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **High-speed peck rigid tapping cycle**
  - In the first cutting from point R, perform cutting by depth "q" specified by address Q while rotating the spindle in the forward direction (operation <1>).
  - Then, perform returning by the amount specified by parameter No. 5213 while rotating the spindle in the reverse direction (operation <2>.)
  - Then, perform tapping by (d+q) while rotating the spindle in the forward direction (operation <3>).

Repeat operations <2> and <3> until the bottom of the hole is reached.

The cutting speed and rigid tapping time constant are used for operations <1> and <3>.

For operation <2> and travel from the bottom of the hole (point Z) to point R, rigid tapping extract override is enabled and the rigid tapping extract time constant is used.
When rigid tapping is specified with G84 (G88) if bit 5 (PCP) of parameter No. 5200 = 1, peck rigid tapping is assumed.

G84 X(U)_ C(H)_Z(W)_ R_ P_ Q_ F_ K_ M_

or

G88 Z(W)_ C(H)_X(U)_ R_ P_ Q_ F_ K_ M_

X_ C_ or Z_ C_ : Hole position data
Z_ or X_ : The distance from point R to the bottom of the hole
R_ : The distance from the initial level to point R level
P_ : Dwell time at the bottom of the hole
Q_ : Depth of cut for each cutting feed
F_ : The cutting feedrate
K_ : Number of repeats (when it is needed.)
M_ : M code for C-axis clamp (when it is needed.)

\[ d = \text{Cutting start distance} \]

- Peck rigid tapping cycle
  In the first cutting from point R, perform cutting by depth “q” specified by address Q while rotating the spindle in the forward direction (operation <1>).
  Then, return to point R by rotating the spindle in the reverse direction (operation <2>).
  Then, rotate the spindle in the forward direction and perform cutting to the position indicated by (Position to which cutting was performed previously) - (Cutting start distance set in parameter No. 5213) as movement to the cutting start point (operation <3>).
  Continue cutting by (d+q) (operation <4>).

Repeat operations <2> to <4> until the bottom of the hole is reached.

The cutting speed and rigid tapping time constant are used for operations <1> and <4>.

For operations <2>, <3>, and travel from the bottom of the hole (point Z) to point R, rigid tapping extract override is enabled and the rigid tapping extract time constant is used.

The symbols in the figure above indicate the following operations.

- : Positioning (Rapid traverse G00)
- : Cutting feed (Linear interpolation G01)
P1 : Dwell programmed by the address P command
M_ : Output of the M code for C-axis clamp (The α value is set in parameter No. 5110.)
M(α+1) : Output of the M code for C-axis unclamp
P2 : Dwell set by parameter No.5111

Note P1, M_ , M(α+1), and P2 are not executed or output without being specified or set.
4. FUNCTIONS TO SIMPLIFY

Explanation

- Cutting start distance
  Cutting start distance \( d \) is set by parameter No. 5213.

- Amount of return
  Amount of return for each time \( d \) is set by parameter No. 5213.

- Return speed
  For the speed of return operation, a maximum of 2000% of override can be enabled by setting DOV (bit 4 of parameter No. 5200), OVU (bit 3 of parameter No. 5201), and parameter No. 5211 as with travel from the bottom of the hole (point Z) to point R.

- Speed during cutting into the cutting start point
  For the speed during cutting into the cutting start point, a maximum of 2000% of override can be enabled by setting DOV (bit 4 of parameter No. 5200), OVU (bit 3 of parameter No. 5201), and parameter No. 5211 as with travel from the bottom of the hole (point Z) to point R.

- Acceleration/deceleration after interpolation
  Linear or bell-shaped acceleration/deceleration can be applied.

- Look-ahead acceleration/deceleration before interpolation
  Look-ahead acceleration/deceleration before interpolation is invalid.

- Override
  Various types of override functions are invalid. The following override functions can be enabled by setting corresponding parameters:
  - Extraction override
  - Override signal
    Details are given later.

- Dry run
  Dry run can be executed also in G84 (G88). When dry run is executed at the feedrate for the drilling axis in G84 (G88), tapping is performed according to the feedrate. Note that the spindle speed becomes faster at a higher dry run feedrate.

- Machine lock
  Machine lock can be executed also in G84 (G88). When G84 (G88) is executed in the machine lock state, the tool does not move along the drilling axis. Therefore, the spindle does not also rotate.

- Reset
  When a reset is performed during rigid tapping, the rigid tapping mode is canceled and the spindle motor enters the normal mode. Note that the G84 (G88) mode is not canceled in this case when bit 6 (CLR) of parameter No. 3402 is set.
- **Interlock**

Interlock can also be applied in G84 (G88).

- **Feed hold and single block**

When parameter FHD (No. 5200#6) is set to 0, feed hold and single block are invalid in the G84 (G88) mode. When this bit is set to 1, they are valid.

- **Manual feed**

For rigid tapping by manual handle feed, see the section "Rigid Tapping by Manual Handle."
With other manual operations, rigid tapping cannot be performed.

- **Backlash compensation**

In the rigid tapping mode, backlash compensation is applied to compensate the lost motion when the spindle rotates clockwise or counterclockwise. Set the amount of backlash in parameters Nos. 5321 to 5324.
Along the drilling axis, backlash compensation has been applied.

- **Series 10/11 format**

When bit 1 (FCV) of parameter No. 0001 is set to 1, execution is enabled with G84.2. The same operation as with G84 is performed. However, the command format for the repetitive count is L.

---

**Limitation**

- **Axis switching**

Before the drilling axis can be changed, the canned cycle must be canceled. If the drilling axis is changed in rigid mode, alarm PS0206 is issued.

- **S commands**

If a speed higher than the maximum speed for the gear being used is specified, alarm PS0200 is issued.
When the rigid tapping canned cycle is cancelled, the S command used for rigid tapping is cleared to S0.

- **Distribution amount for the spindle**

The maximum distribution amount is 32,767 pulses per 8 msec for a serial spindle. (displayed on diagnostic display No. 451)
This amount is changed according to the gear ratio setting for the position coder or rigid tapping command. If a setting is made to exceed the upper limit, alarm PS0202 is issued.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

- **F command**

Specifying a value larger than the upper limit for cutting feed will cause alarm PS0011 to be issued.

- **Unit of F command**

<table>
<thead>
<tr>
<th>Metric input</th>
<th>Inch input</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>G98</td>
<td>1mm/min</td>
<td>0.01inch/min</td>
</tr>
<tr>
<td>G99</td>
<td>0.01mm/rev</td>
<td>0.0001inch/rev</td>
</tr>
</tbody>
</table>

- **M29**

If an S command and axis movement are specified between M29 and G84, alarm PS0203 is issued. If M29 is specified in a tapping cycle, alarm PS0204 is issued.

- **Rigid tapping command M code**

The M code used to specify the rigid tapping mode is set in parameter No. 5210.

- **P/Q**

Specify P and Q in a block that performs drilling. If they are specified in a block that does not perform drilling, they are not stored as modal data.

When Q0 is specified, the peck rigid tapping cycle is not performed.

- **Cancel**

Do not specify a G code of the 01 group (G00 to G03) and G84 in a single block. Otherwise, G84 will be canceled.

- **Tool offset**

In the canned cycle mode, tool offsets are ignored.

- **Subprogram call**

In the canned cycle mode, specify the subprogram call command M98P_ in an independent block.

- **d (parameter No.5213)**

Perform operation in the peck tapping cycle within point R. That is, set a value which does not exceed point R for d (parameter No. 5213).
4.4.3 Canned Cycle Cancel (G80)

The rigid tapping canned cycle is canceled. For how to cancel this cycle, see II-4.3.4.

NOTE
When the rigid tapping canned cycle is cancelled, the S value used for rigid tapping is also cleared (as if S0 is specified). Accordingly, the S command specified for rigid tapping cannot be used in a subsequent part of the program after the cancellation of the rigid tapping canned cycle. After canceling the rigid tapping canned cycle, specify a new S command as required.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.4.4 Override during Rigid Tapping

Various types of override functions are invalid. The following override functions can be enabled by setting corresponding parameters:
- Extraction override
- Override signal

4.4.4.1 Extraction override

For extraction override, the fixed override set in the parameter or override specified in a program can be enabled at extraction (including retraction during peck drilling/high-speed peck drilling).

Explanation

- Specifying the override in the parameter
  Set bit 4 (DOV) of parameter No. 5200 to 1 and set the override in parameter No. 5211.
  An override from 0% to 200% in 1% steps can be set. Bit 3 (OVU) of parameter No. 5201 can be set to 1 to set an override from 0% to 2000% in 10% steps.

- Specifying the override in a program
  Set bit 4 (DOV) of parameter No. 5200 and bit 4 (OV3) of parameter No. 5201 to 1. The spindle speed at extraction can be specified in the program.
  Specify the spindle speed at extraction using address "J" in the block in which rigid tapping is specified.
  Example)
  To specify 1000 min⁻¹ for S at cutting and 2000 min⁻¹ for S at extraction
  .
  M29 S1000 ;
  G84 Z-100. F1000. J2000 ;
  .

The difference in the spindle speed is converted to the actual override by the following calculation.
Therefore, the spindle speed at extraction may not be the same as that specified at address "J". If the override does not fall in the range between 100% and 200%, it is assumed to be 100%.

\[
\text{Override (\%)} = \frac{\text{Spindle speed at extraction (specified at J)}}{\text{Spindle speed (specified at S)}} \times 100
\]

Bit 6 (OVE) of parameter No. 5202 can be set to 1 to extend the override value to 100% to 2000%. If the specified override value is outside the range between 100% and 200%, it is assumed to be 100%.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

The override to be applied is determined according to the setting of parameters and that in the command as shown in the table below.

When bit 6 (OVE) of parameter No. 5202 is set to 0

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter setting</th>
<th>DOV=1</th>
<th>DOV=0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spindle speed at extraction specified at address J</td>
<td>Within the range between 100 to 200%</td>
<td>Command in the program</td>
<td>Parameter No. 5211</td>
</tr>
<tr>
<td>No spindle speed at extraction specified at address J</td>
<td>Within the range between 100 to 200%</td>
<td>100%</td>
<td></td>
</tr>
</tbody>
</table>

When bit 6 (OVE) of parameter No. 5202 is set to 1

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter setting</th>
<th>DOV=1</th>
<th>DOV=0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spindle speed at extraction specified at address J</td>
<td>Within the range between 100 to 2000%</td>
<td>Command in the program</td>
<td>Parameter No. 5211</td>
</tr>
<tr>
<td>No spindle speed at extraction specified at address J</td>
<td>Within the range between 100 to 2000%</td>
<td>100%</td>
<td></td>
</tr>
</tbody>
</table>

NOTE
1. Do not use a decimal point in the value specified at address "J". If a decimal point is used, the value is assumed as follows:
   - When the increment system for the reference axis is IS-B
     - When pocket calculator type decimal point programming is not used
       The specified value is converted to the value for which the least input increment is considered.
       "J200." is assumed to be 200000 min^{-1}.
     - When pocket calculator type decimal point programming is used
       The specified value is converted to the value obtained by rounding down to an integer.
       "J200." is assumed to be 200 min^{-1}.
2. Do not use a minus sign in the value specified at address "J". If a minus sign is used, a value outside the range is assumed to be specified.
3. The maximum override is obtained using the following equation so that the spindle speed to which override at extraction is applied do not exceed the maximum used gear speed (specified in parameters Nos. 5241 to 5244). For this reason, the obtained value is not the same as the maximum spindle speed depending on the override.
   \[
   \text{Maximum override (\%) } = \frac{\text{Maximum spindle speed (specified in parameters)}}{\text{Spindle speed (specified at S)}} \times 100
   \]
4. When a value is specified at address "J" for specifying the spindle speed at extraction in the rigid tapping mode, it is valid until the canned cycle is canceled.
4.4.4.2 Override signal

By setting bit 4 (OVS) of parameter No. 5203 to 1, override can be applied to cutting/extraction operation during rigid tapping as follows:

- Applying override using the feedrate override signal
- Canceling override using the override cancel signal

There are the following relationships between this function and override to each operation:

- **At cutting**
  - When the override cancel signal is set to 0
    Value specified by the override signal
  - When the override cancel signal is set to 1
    100%

- **At extraction**
  - When the override cancel signal is set to 0
    Value specified by the override signal
  - When the override cancel signal is set to 1 and extraction override is disabled
    100%
  - When the override cancel signal is set to 1 and extraction override is enabled
    Value specified for extraction override

### NOTE

1. The maximum override is obtained using the following equation so that the spindle speed to which override is applied do not exceed the maximum used gear speed (specified in parameters Nos. 5241 to 5244). For this reason, the obtained value is not the same as the maximum spindle speed depending on the override.

\[
\text{Maximum override (\%)} = \frac{\text{Maximum spindle speed (specified in parameters)}}{\text{Spindle speed (specified at \text{S})}} \times 100
\]

2. Since override operation differs depending on the machine in use, refer to the manual provided by the machine tool builder.
4.5 CANNED GRINDING CYCLE (FOR GRINDING MACHINE)

With the canned grinding cycle, repetitive machining operations that are specific to grinding and are usually specified using several blocks can be specified using one block including a G function. So, a program can be created simply. At the same time, the size of a program can be reduced, and the memory can be used more efficiently. Four types of canned grinding cycles are available:

- Traverse grinding cycle (G71)
  (G72 when G code system C is used)
- Traverse direct constant-size grinding cycle (G72)
  (G73 when G code system C is used)
- Oscillation grinding cycle (G73)
  (G74 when G code system C is used)
- Oscillation direct constant-size grinding cycle (G74)
  (G75 when G code system C is used)

In the descriptions below, an axis used for cutting with a grinding wheel and an axis used for grinding with a grinding wheel are referred to as follows:

Axis used for cutting with a grinding wheel: Cutting axis
Axis used for grinding with a grinding wheel: Grinding axis

For a depth of cut on a cutting axis and a distance of grinding on a grinding axis, the incremental system (parameter No. 1013) for the reference axis (parameter No. 1031) is used. If 0 is set in parameter No. 1031 (reference axis), the incremental system for the first axis is used.

NOTE
The canned grinding cycle is an optional function.
The canned grinding cycle and multiple repetitive cycle cannot be used simultaneously for the same path.
To use the canned grinding cycle, set bit 0 (GFX) of parameter No. 5106 to 1.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

WARNING

The G codes for canned grinding cycles G71, G72, G73, and G74 (G72, G73, G74, and G75 when G code system C is used) are G codes of group 01. A G code for cancellation such as G80 used for a canned cycle for drilling is unavailable. By specifying a G code of group 00 other than G04, modal information such as a depth of cut is cleared but no canned grinding cycle can be canceled. To cancel a canned grinding cycle, a G code of group 01 other than G71, G72, G73, and G74 needs to be specified. So, when switching to another axis move command from G71, G72, G73 or G74, for example, be sure to specify a G code of group 01 such as G00 or G01 to cancel the canned grinding cycle. If another axis move command is specified without canceling the canned grinding cycle, an unpredictable operation can result because of continued cycle operation.

NOTE

1. If the G code for a canned grinding cycle (G71, G72, G73, or G74) is specified, the canned grinding cycle is executed according to the values of A, B, W, U, I, and K preserved as modal data while the cycle is valid, even if a block specified later specifies none of G71, G72, G73, and G74. Example:

   \[ G71 \ A_ \ B_ \ W_ \ U_ \ I_ \ K_ \ H_ ; \]
   \[ ; \quad \leftarrow \text{The canned grinding cycle is executed}
   \quad \text{even if an empty block is specified.} \]

2. When switching from a canned cycle for drilling to a canned grinding cycle, specify G80 to cancel the canned cycle for drilling.

3. When switching from a canned grinding cycle to another axis move command, cancel the canned cycle according to the warning above.

4. A canned grinding cycle and multiple repetitive canned cycle cannot be used simultaneously on the same path.

   When the canned grinding cycle option is enabled, which function is to be used can be selected using bit 0 (GFX) of parameter No. 5106.
4.5.1 **Traverse Grinding Cycle (G71)**

A traverse grinding cycle can be executed.

**Format**

<table>
<thead>
<tr>
<th>G71 A_ B_ W_ U_ I_ K_ H_ ;</th>
</tr>
</thead>
<tbody>
<tr>
<td>A_ : First depth of cut (The cutting direction depends on the sign.)</td>
</tr>
<tr>
<td>B_ : Second depth of cut (The cutting direction depends on the sign.)</td>
</tr>
<tr>
<td>W_ : Grinding range (The grinding direction depends on the sign.)</td>
</tr>
<tr>
<td>U_ : Dwell time</td>
</tr>
<tr>
<td>I_ : Feedrate for A and B</td>
</tr>
<tr>
<td>K_ : Feedrate for W</td>
</tr>
<tr>
<td>H_ : Repetitive count (from 1 to 9999)</td>
</tr>
</tbody>
</table>

![Diagram of G71 cycle](image)
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Explanation

The traverse grinding cycle consists of six operations. The operations from <1> to <6> are repeated until the repetitive count specified in address H is reached. In the case of single block operation, the operations from <1> to <6> are executed with one cycle start operation.

- Operation sequence in a cycle
  <1> Cutting with a grinding wheel
      By the first depth of cut specified in A, cutting is performed by cutting feed in the X-axis direction. The feedrate specified in I is used.
  <2> Dwell
      A dwell operation is performed for the time specified in U.
  <3> Grinding
      A movement is made by the distance specified in W by cutting feed. Set a grinding axis in parameter No.5176. The feedrate specified in K is used.
  <4> Cutting with a grinding wheel
      By the second depth of cut specified in B, cutting is performed by cutting feed in the X-axis direction. The feedrate specified in I is used.
  <5> Dwell
      A dwell operation is performed for the time specified in U.
  <6> Grinding (return direction)
      A movement is made at the feedrate specified in K in the reverse direction by the distance specified in W.
Limitation

- Cutting axis

As a cutting axis, the first controlled axis is used. By setting bit 0 (FXY) of parameter No. 5101 to 1, the axis can be switched using a plane selection command (G17, G18, or G19).

- Grinding axis

Specify a grinding axis by setting an axis number for other than the cutting axis in parameter No. 5176. Specify a grinding command in W at all times without using an axis name. The axis name corresponding to the set axis number can also be used for specification.

- A, B, W

The commands of A, B, and W are all incremental commands. When none of A and B are specified or A=B=0, spark-out operation (execution of only movement in the grinding direction) is performed.

- H

When H is not specified or H=0, the specification of H=1 is assumed. The specification of H is valid only in the block where H is specified.

- Clear

The data A, B, W, U, I, and K in the canned cycle is modal information common to G71, G72, G73, and G74. So, the data remains valid until new data is specified. The data is cleared when a G code of group 00 other than G04 or a G code of group 01 other than G71, G72, G73, and G74 is specified. The specification of H is valid only in the block where H is specified.

- B code

During the canned cycle, no B code (second auxiliary function) can be specified.

NOTE

1. If no grinding axis is specified when G71 is specified, alarm PS0455 is issued.
2. If the specified cutting axis number and grinding axis number are the same, alarm PS0456 is issued.
3. Even if G90 (absolute command) is specified while this cycle is valid, each of the A, B, and W commands is an incremental command.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

4.5.2 Traverse Direct Constant-Size Grinding Cycle (G72)

A traverse direct constant-size grinding cycle can be executed.

**Format**

\[
\text{G72 P\_ A\_ B\_ W\_ U\_ I\_ K\_ H\_;}
\]

- **P\_**: Gage number (1 to 4)
- **A\_**: First depth of cut (The cutting direction depends on the sign.)
- **B\_**: Second depth of cut (The cutting direction depends on the sign.)
- **W\_**: Grinding range (The grinding direction depends on the sign.)
- **U\_**: Dwell time
- **I\_**: Feedrate for A and B
- **K\_**: Feedrate for W
- **H\_**: Repetitive count (from 1 to 9999)

![Diagram of Traverse Direct Constant-Size Grinding Cycle (G72)]
Explanation

If the multi-step skip option is specified, a gage number can be specified. The method of gage number specification is the same as for the multi-step skip option. If the multi-step skip option is not specified, the conventional skip signal is used.

The commands and operations other than gage number specification are the same as for G71.

- **Operation performed when the skip signal is input**

A G72 cycle can be terminated after interrupting the current operation (or after ending the current operation) by inputting the skip signal during execution of the cycle.

Each operation of the sequence performed when the skip signal is input is described below.

- If the skip signal is input during operation <1> or <4> (movement by A or B), cutting is immediately stopped to return to coordinate $\alpha$ selected as the cycle start point.

- If the skip signal is input during operation <2> or <5> (dwell), dwell operation is immediately stopped to return to coordinate $\alpha$ selected as the cycle start point.

- If the skip signal is input during operation <3> or <6> (grinding feed), the tool returns to coordinate $\alpha$ selected as the cycle start point after the end of movement over W.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Limitation

- Cutting axis

As a cutting axis, the first controlled axis is used. By setting bit 0 (FXY) of parameter No. 5101 to 1, the axis can be switched using a plane selection command (G17, G18, or G19).

- Grinding axis

Specify a grinding axis by setting an axis number for other than the cutting axis in parameter No. 5177. Specify a grinding command in W at all times without using an axis name. The axis name corresponding to the set axis number can also be used for specification.

- P

If a value other than P1 to P4 is specified, the skip function is disabled.
The specification of P is valid only in the block where P is specified.

- A, B, W

The commands of A, B, and W are all incremental commands.
When none of A and B are specified or A=B=0, spark-out operation (execution of only movement in the grinding direction) is performed.

- H

When H is not specified or H=0, the specification of H=1 is assumed.
The specification of H is valid only in the block where H is specified.

- Clear

The data A, B, W, U, I, and K in the canned cycle is modal information common to G71, G72, G73, and G74. So, the data remains valid until new data is specified. The data is cleared when a G code of group 00 other than G04 or a G code of group 01 other than G71, G72, G73, and G74 is specified. The specification of P or H is valid only in the block where P or H is specified.

- B code

During the canned cycle, no B code (second auxiliary function) can be specified.

NOTE

1. If no grinding axis is specified when G72 is specified, alarm PS0455 is issued.
2. If the specified cutting axis number and grinding axis number are the same, alarm PS0456 is issued.
3. Even if G90 (absolute command) is specified while this cycle is valid, each of the A, B, and W commands is an incremental command.
4. If a value from P1 to P4 is specified without specifying the multi-step skip option, alarm PS0370 is issued.
4.5.3 Oscillation Grinding Cycle (G73)

An oscillation grinding cycle can be executed.

**Format**

```
G73 A_ (B_) W_ U_ K_ H_ ;
```

- **A_**: First depth of cut (The cutting direction depends on the sign.)
- **B_**: Second depth of cut (The cutting direction depends on the sign.)
- **W_**: Grinding range (The grinding direction depends on the sign.)
- **U_**: Dwell time
- **K_**: Feedrate for W
- **H_**: Repetitive count (from 1 to 9999)
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Explanation

The oscillation grinding cycle consists of four operations. The operations from <1> to <4> are repeated until the repetitive count specified in address H is reached. In the case of single block operation, the operations from <1> to <4> are executed with one cycle start operation.

- Operation sequence in a cycle

  <1>  Dwell

  A dwell operation is performed for the time specified in U.

  <2>  Cutting + grinding with a grinding wheel

  Cutting feed is performed on the cutting axis (X-axis) and a grinding axis at the same time. The amount of movement on the cutting axis (depth of cut) is the first depth of cut specified in A, and the amount of movement on a grinding axis is the distance specified in W. Set a grinding axis in parameter No.5178. The feedrate specified in K is used.

  <3>  Dwell

  A dwell operation is performed for the time specified in U.

  <4>  Cutting + grinding with a grinding wheel (return direction)

  Cutting feed is performed on the cutting axis (X-axis) and a grinding axis at the same time. The amount of movement on the cutting axis (depth of cut) is the second depth of cut specified in B, and the amount of movement on the grinding axis is the distance specified in W. The feedrate specified in K is used.
Limitation

- Cutting axis

As a cutting axis, the first controlled axis is used. By setting bit 0 (FXY) of parameter No. 5101 to 1, the axis can be switched using a plane selection command (G17, G18, or G19).

- Grinding axis

Specify a grinding axis by setting an axis number for other than the cutting axis in parameter No. 5178. Specify a grinding command in W at all times without using an axis name. The axis name corresponding to the set axis number can also be used for specification.

- B

If B is not specified, B=A is assumed. The specification of B is valid only in the block where B is specified.

- A, B, W

The commands of A, B, and W are all incremental commands. When none of A and B are specified or A=B=0, spark-out operation (execution of only movement in the grinding direction) is performed.

- H

When H is not specified or H=0, the specification of H=1 is assumed. The specification of H is valid only in the block where H is specified.

- Clear

The data A, W, U, and K in the canned cycle is modal information common to G71, G72, G73, and G74. So, the data remains valid until new data is specified. The data is cleared when a G code of group 00 other than G04 or a G code of group 01 other than G71, G72, G73, and G74 is specified. The specification of B or H is valid only in the block where B or H is specified.

- B code

During the canned cycle, no B code (second auxiliary function) can be specified.

NOTE

1. If no grinding axis is specified when G73 is specified, alarm PS0455 is issued.
2. If the specified cutting axis number and grinding axis number are the same, alarm PS0456 is issued.
3. Even if G90 (absolute command) is specified while this cycle is valid, each of the A, B, and W commands is an incremental command.
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

4.5.4 Oscillation Direct Constant-Size Grinding Cycle (G74)

An oscillation direct constant-size grinding cycle can be executed.

Format

G74 P_ A_ (B_) W_ U_ K_ H_ ;

P_ : Gage number (1 to 4)
A_ : First depth of cut (The cutting direction depends on the sign.)
B_ : Second depth of cut (The cutting direction depends on the sign.)
W_ : Grinding range (The grinding direction depends on the sign.)
U_ : Dwell time
K_ : Feedrate for W
H_ : Repetitive count (from 1 to 9999)
Explanation

If the multi-step skip option is specified, a gage number can be specified. The method of gage number specification is the same as for the multi-step skip option. If the multi-step skip option is not specified, the conventional skip signal is used.

The commands and operations other than gage number specification are the same as for G73.

- **Operation performed when the skip signal is input**

A G74 cycle can be terminated after interrupting the current operation (or after ending the current operation) by inputting the skip signal during execution of the cycle.

Each operation of the sequence performed when the skip signal is input is described below.

- If the skip signal is input during operation <1> or <3> (dwell), dwell operation is immediately stopped to return to coordinate α selected as the cycle start point.
- If the skip signal is input during operation <2> or <4> (A, B, grinding feed), the tool returns to coordinate α selected as the cycle start point after the end of movement over W.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

Limitation

- Cutting axis

As a cutting axis, the first controlled axis is used. By setting bit 0 (FXY) of parameter No. 5101 to 1, the axis can be switched using a plane selection command (G17, G18, or G19).

- Grinding axis

Specify a grinding axis by setting an axis number for other than the cutting axis in parameter No. 5179. Specify a grinding command in W at all times without using an axis name. The axis name corresponding to the set axis number can also be used for specification.

- P

If a value other than P1 to P4 is specified, the skip function is disabled.
The specification of P is valid only in the block where P is specified.

- B

If B is not specified, B=A is assumed.
The specification of B is valid only in the block where B is specified.

- A, B, W

The commands of A, B, and W are all incremental commands. When none of A and B are specified or A=B=0, spark-out operation (execution of only movement in the grinding direction) is performed.

- H

When H is not specified or H=0, the specification of H=1 is assumed.
The specification of H is valid only in the block where H is specified.

- Clear

The data A, W, U, and K in the canned cycle is modal information common to G71, G72, G73, and G74. So, the data remains valid until new data is specified. The data is cleared when a G code of group 00 other than G04 or a G code of group 01 other than G71, G72, G73, and G74 is specified. The specification of P, B, or H is valid only in the block where P, B, or H is specified.

- B code

During the canned cycle, no B code (second auxiliary function) can be specified.

NOTE

1. If no grinding axis is specified when G74 is specified, alarm PS0455 is issued.
2. If the specified cutting axis number and grinding axis number are the same, alarm PS0456 is issued.
3. Even if G90 (absolute command) is specified while this cycle is valid, each of the A, B, and W commands is an incremental command.
4. If a value from P1 to P4 is specified without specifying the multi-step skip option, alarm PS0370 is issued.
4.6 CHAMFERING AND CORNER R

Overview

A chamfering or corner R block can automatically be inserted between linear interpolation (G01) along a single axis and that along a single axis normal to that single axis. Chamfering or corner R is inserted for a command to move the tool along two axes on the plane determined by the plane selection (G17, G18, or G19) command.

NOTE

To enable the chamfering and corner R function, bit 2 (CCR) of parameter No. 8134 to 1.

Format

- Chamfering

Moves from a to d and c.
(Positive direction along the first axis on the selected plane when \( +r \) is specified at R or negative direction when \( -r \) is specified at R)

![Diagram](https://via.placeholder.com/150)
### Explanation

By G01 specified for chamfering or corner R, the tool must be moved only along one of the two axes on the selected plane. The command in the next block must move the tool only along the other axis on the selected plane.

**Example:**

When the A-axis is set as an axis parallel to the basic X-axis (by setting parameter No. 1022 to 5), the following program performs chamfering between cutting feed along the A-axis and that along the Z-axis:

```
G18 A0 Z0
G00 A100.0 Z100.0
G01 A200.0 F100 K30.0 Z200.0
```

The following program causes an alarm. (Because chamfering is specified in the block to move the tool along the X-axis, which is not on the selected plane)

```
G18 A0 Z0
G00 A100.0 Z100.0
G01 X200.0 F100 K30.0 Z200.0
```

The following program also causes an alarm. (Because the block next to the chamfering command moves the tool along the X-axis, which is not on the selected plane)

```
G18 A0 Z0
G00 A100.0 Z100.0
G01 Z200.0 F100 130.0 X200.0
```

A radius value is specified at I, J, K, R, and C.

In an incremental programming, use point b in the figure in "Format" as the start point in the block next to a chamfering or corner R block. That is, specify the distance from point b. Do not specify the distance from point c.

---

**Example**

```
N001 G18 ;
N002 G00 X268.0 Z530.0 ;
N003 G01 Z270.0 R6.0 ;
N004 X860.0 K-3.0 ;
N005 Z0 ;
```

---

[Diagram of cutting start point and end point with X and Z axes labeled]
4. FUNCTIONS TO SIMPLIFY

PROGRAMMING

Limitation - Alarms

In the following cases, an alarm is issued:

1) Chamfering or corner R is specified in a block for threading (alarm PS0050).

2) G01 is not specified in the block next to the G01 block in which chamfering or corner R is specified (alarm PS0051 or PS0052).

3) An axis which is not on the selected plane is specified as a move axis in the block in which chamfering or corner R is specified or the next block (alarm PS0051 or PS0052).

4) A plane selection command (G17, G18, or G19) is specified in the block next to the block in which chamfering or corner R is specified (alarm PS0051).

5) When bit 4 (CCR) of parameter No. 3405 is set to 0 (to specify chamfering at I, J, or K), two or more of I, J, K, and R are specified in G01 (alarm PS0053).

6) Chamfering or corner R is specified in the G01 block to move the tool along more than one axis (alarm PS0054).

7) The travel distance along an axis specified in the block in which chamfering or corner R is specified is smaller than the amount of chamfering or corner R (alarm PS0055). (See the figure below.)

8) An invalid combination of a move axis and I, J, or K is specified for chamfering (alarm PS0306).

Fig. 4.6 (a) Example of machining which causes alarm PS0055
9) An invalid sign is specified at I, J, K, R, or C (chamfering or corner R in the direction opposite to the movement in the next block is specified) (alarm PS0051). (See the figure below.)

![Diagram of tool path and chamfering block](image)

**Fig. 4.6 (b) Example of machining which causes alarm PS0051**

- **Single block operation**

When the block in which chamfering or corner R is specified is executed in the single block mode, operation continues to the end point of the inserted chamfering or corner R block and the machine stops in the feed hold mode at the end point. When bit 0 (SBC) of parameter No. 5105 is set to 1, the machine stops in the feed hold mode also at the start point of the inserted chamfering or corner R block.

- **Tool nose radius compensation**

When applying tool nose radius compensation, note the following points:

1. If the amount of inner chamfering or corner R is too small as compared with compensation and cutting is generated, alarm PS0041 is issued. (See the figure below.)

![Diagram of programmed path and tool center path](image)

Example of machining which does not cause alarm PS0041

Example of machining which causes alarm PS0041

(The solid line indicates the programmed path after chamfering. The dotted line indicates the tool center path or tool nose radius center path.)

2. A function is available which intentionally changes the compensation direction by specifying the I, J, or K command in the G01 block in the tool nose radius compensation mode (see the explanations of tool nose radius compensation). To use this function when the chamfering and corner R function is enabled (bit 2 (CCR) of parameter No. 8134 is set to 1), set bit 4 (CCR) of parameter No. 3405 is set to 1 so that the I, J, and K commands are not used as chamfering commands. Operation to be performed under each condition is explained below.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

(1) When the chamfering and corner R function is not used (bit 2 (CCR) of parameter No.8134 = 0)
   In the G01 block in the tool nose radius compensation mode, the tool nose radius compensation direction can be specified at address I, J, or K.
   No chamfering is performed.

(2) When the chamfering and corner R function is used (bit 2 (CCR) of parameter No.8134 = 1)
   (2-1) When bit 4 (CCR) of parameter No. 3405 is set to 0
         In the G01 block in the tool nose radius compensation mode, chamfering can be specified at address I, J, or K.
         Corner R can also be specified at address R.
         The tool nose radius compensation direction cannot be specified.
   (2-2) When bit 4 (CCR) of parameter No. 3405 is set to 1
         In the G01 block in the tool nose radius compensation mode, the tool nose radius compensation direction can be specified at address I, J, or K.
         Chamfering or corner R can also be specified at address C or R.

- Direct drawing dimension programming

The chamfering and corner R function and direct drawing dimension programming cannot be used simultaneously.
When the chamfering and corner R function is enabled (bit 2 (CCR) of parameter No. 8134 is set to 1), bit 0 (CRD) of parameter No. 3453 can be set to 1 to enable direct drawing dimension programming.
(With this setting, the chamfering and corner R function is disabled.)
4.7 MIRROR IMAGE FOR DOUBLE TURRET (G68, G69)

Overview

When a unit has a double turret consisting of two tool posts which face each other on the same controlled axis, mirror image can be applied to the X-axis with a G code command. Symmetrical cutting can be performed by creating a machining program for the facing tool posts as if they were in the coordinate system on the same side.

Format

<table>
<thead>
<tr>
<th>G68</th>
<th>Double turret mirror image on</th>
</tr>
</thead>
<tbody>
<tr>
<td>G69</td>
<td>Mirror image cancel</td>
</tr>
</tbody>
</table>

Explanation

Mirror image can be applied to the X-axis of the three basic axes that is set by parameter No. 1022 with the G code command. When G68 is designated, the coordinate system is shifted to the double turret side, and the X-axis sign is reversed from the programmed command to perform symmetrical cutting. This function is called the mirror image for double turret. To use this function, set the distance between the two tool posts to a parameter No. 1290.

Example

- For turning

![Diagram of mirror image for double turret](image-url)
4. FUNCTIONS TO SIMPLIFY
PROGRAMMING

4. FUNCTIONS TO SIMPLIFY

PROGRAMMING

X40.0 Z180.0 T0101 ; Position tool post A at <1>
G68 ; Shift the coordinate system by the distance A to B
(120mm), and turn mirror image on.
X80.0 Z120.0 T0202 ; Position tool post B at <2>
G69 ; Shift the coordinate system by the distance B to A,
and cancel mirror image.
X120.0 Z60.0 T0101 ; Position tool post A at <3>

NOTE
A diameter value is specified for the X-axis.

Limitation

NOTE
1 When the G68 command based on this function is
enabled, the X-axis coordinate value that can be
read with the custom macro system variables
#5041 and up or #100101 and up (current specified
position (in the workpiece coordinate system)) is a
position with mirror image applied.
2 This function cannot be used together with the
balanced cutting function (for a 2-path system).
To use this function, set bit 0 (NVC) of parameter
No. 8137 to 1.
4.8 DIRECT DRAWING DIMENSION PROGRAMMING

Overview

Angles of straight lines, chamfering value, corner R values, and other dimensional values on machining drawings can be programmed by directly inputting these values. In addition, the chamfering and corner R can be inserted between straight lines having an optional angle. This programming is only valid in memory operation mode.

**NOTE**

To use direct drawing dimension programming when the chamfering and corner R function is enabled (bit 2 (CCR) of parameter No. 8134 is set to 1), set bit 0 (CRD) of parameter No. 3453 to 1. (With this setting, the chamfering and corner R function is disabled.)

Format

Examples of command formats for the G18 plane (ZX plane) are shown. This function can be specified in the following formats also for the G17 plane (XY plane) and G19 plane (YZ plane).

The following formats are changed as follows:
- For the G17 plane: Z → X, X → Y
- For the G19 plane: Z → Y, X → Z

<td>X4, Z4;</td>
<td>(X1, Z1)</td>
</tr>
</tbody>
</table>

#### Explanation

A program for machining along the curve shown in Fig. 4.8 (a) is as follows:

For command a straight line, specify one or two out of X, Z, and A. If only one is specified, the straight line must be primarily defined by a command in the next block.

To command the degree of a straight line or the value of chamfering or corner R, command with a comma (,) as follows:

- A
- C
- R

By specifying 1 to bit 4 (CCR) of parameter No.3405 on the system which does not use A or C as an axis name, the degree of a straight line or the value of chamfering or corner R can be commanded without a comma (,) as follows:

- A
- C
- R

**Fig. 4.8 (a) Machining Drawing (example)**
- Command using a supplement

When bit 5 (DDP) of parameter No. 3405 is set to 1, an angle can be specified using a supplement.
There is the following relationship, assuming that the supplement is A’ and the actual specified angle is A:

\[ A = 180 - A' \]

![Fig. 4.8 (b) Supplement](image)

Limitation

**NOTE**

1. Direct drawing dimension programming commands are valid only during memory operation.
2. The following G codes are not applicable to the same block as commanded by direct input of drawing dimensions or between blocks of direct input of drawing dimensions which define sequential figures.
   (a) G codes other than G04 in group 00
   (b) G codes other than G00, G01, and G33 in group 01
   (c) G codes in group 10 (canned cycle for drilling)
   (d) G codes in group 16 (plane selection)
   (e) G22 and G23
3. Corner R cannot be inserted into a threading block.
4. When the chamfering and corner R function is enabled (bit 2 (CCR) of parameter No. 8134 is set to 1), both functions cannot be used simultaneously. When bit 0 (CRD) of parameter No. 3453 is set to 1, direct drawing dimension programming is enabled. (At this time, chamfering and corner R are disabled.)
5. When the end point of the previous block is determined in the next block according to sequential commands of direct drawing dimension programming during single block operation, the machine does not stop in the single block stop mode, but stop in the feed hold stop mode at the end point of the previous block.
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

NOTE

6. The angle allowance in calculating the point of intersection in the program below is ±1°.
   (Because the travel distance to be obtained in this calculation is too large.)
   (a) X_,A_; (If a value within 0°±1° or 180°±1° is specified for the angle instruction A, the alarm PS0057 occurs.)
   (b) Z_,A_; (If a value within 90°±1° or 270°±1° is specified for the angle instruction A, the alarm PS0057 occurs.)

7. An alarm PS0058 occurs if the angle made by the 2 lines is within ±1° when calculating the point of intersection.

8. Chamfering or corner R is ignored if the angle made by the 2 lines is within ±1°.

9. Both a dimensional command (absolute programming) and angle instruction must be specified in the block following a block in which only the angle instruction is specified.
   (Example)
   
   N1 X_,A_,R_;  
   N2 ,A_;  
   N3 X_,Z_,A_;  

   In addition to the dimensional command, angle command must be specified in block No. 3. If the angle command is not specified, alarm PS0056 is issued. If the coordinates are not specified with an absolute programming, alarm PS0312 is issued.

10. In the tool nose radius compensation mode, a block in which only the angle command is specified in direct drawing dimension programming is assumed to be a block with no move command. For details of compensation when sequential blocks with no move command are specified, see the explanation of tool nose radius compensation.

11. If two or more blocks with no move command are specified between sequential commands of direct drawing dimension programming, alarm PS0312 is issued.

12. When bit 4 (CCR) of parameter No. 3405 is set to 1, address A in the G76 (multiple threading cycle) block specifies the tool nose angle.
    When A or C is used as an axis name, it cannot be used in the angle or chamfering command in direct drawing dimension programming. Use ,A_ or ,C_ (when bit 4 (CCR) of parameter No. 3405 is set to 0).
4. FUNCTIONS TO SIMPLIFY PROGRAMMING

NOTE
13 In a multiple repetitive canned cycle, in blocks with sequence numbers between those specified at P and Q, a program using direct drawing dimension programming can be used. The block with the last sequence number specified at Q must not be an intermediate block of these specified blocks.

Example

(Diameter specification, metric input)

N001 G50 X0.0 Z0.0 ;
N002 G01 X60.0 ,A90.0 ,C1.0 F80 ;
N003 Z-30.0 ,A180.0 ,R6.0 ;
N004 X100.0 ,A90.0 ;
N005 A170.0 ,R20.0 ;
N006 X300.0 Z-180.0 ,A112.0 ,R15.0 ;
N007 Z-230.0 A180.0 ;
...
Chapter 5, "COMPENSATION FUNCTION", consists of the following sections:

5.1 TOOL OFFSET..................................................................................162
5.2 OVERVIEW OF TOOL NOSE RADIUS COMPENSATION
(G40-G42)......................................................................................168
5.3 DETAILS OF TOOL NOSE RADIUS COMPENSATION.....185
5.4 CORNER CIRCULAR INTERPOLATION (G39) .................242
5.5 AUTOMATIC TOOL OFFSET (G36, G37) .........................244
5.1 TOOL OFFSET

Tool offset is used to compensate for the difference when the tool actually used differs from the imagined tool used in programming (usually, standard tool).

![Tool offset diagram](image)

5.1.1 Tool Geometry Offset and Tool Wear Offset

Tool geometry offset and tool wear offset are possible to divide the tool offset to the tool geometry offset for compensating the tool shape or tool mounting position and the tool wear offset for compensating the tool nose wear. The tool geometry offset value and tool wear offset value can be set individually. When these values are not distinguished from each other, the total of the values is set as the tool offset value.

![Tool offset diagram](image)
5.1.2 T Code for Tool Offset

Format

Select a tool with a numeric value after a T code. A part of the numeric value is used as a tool offset number for specifying data such as a tool offset value. The following selections can be made according to the specification method and parameter setting:

<table>
<thead>
<tr>
<th>Meaning of T code (*1)</th>
<th>Parameter setting for specifying of offset No. (*2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGN(No.5002#1)=0</td>
<td>A tool wear offset number is specified using the lower one digit of a T code.</td>
</tr>
<tr>
<td>LGN(No.5002#1)=1</td>
<td>When parameter No. 5028 is set to 1</td>
</tr>
<tr>
<td>Txxxxxx y</td>
<td>When parameter No. 5028 is set to 2</td>
</tr>
<tr>
<td>xxxxxx : Tool selection</td>
<td></td>
</tr>
<tr>
<td>y : Tool wear and tool geometry offset y : Tool wear offset</td>
<td></td>
</tr>
<tr>
<td>Txxxxxx yy</td>
<td></td>
</tr>
<tr>
<td>xxxxxx : Tool selection</td>
<td></td>
</tr>
<tr>
<td>yy : Tool wear and tool geometry offset yy : Tool wear offset</td>
<td></td>
</tr>
<tr>
<td>Txxxxxx yyyy</td>
<td></td>
</tr>
<tr>
<td>xxxxx : Tool selection</td>
<td></td>
</tr>
<tr>
<td>yyyy : Tool wear and tool geometry offset yyyy : Tool wear offset</td>
<td></td>
</tr>
</tbody>
</table>

*1 The maximum number of digits of a T code can be specified using parameter No. 3032. (1 to 8 digits)
*2 When parameter No. 5028 is set to 0, the number of digits of a T code used for offset number specification depends on the number of tool offsets.
  Example)
  When the number of tool offsets is 1 to 9: Lower one digit
  When the number of tool offsets is 10 to 99: Lower two digits
  When the number of tool offsets is 100 to 200: Lower three digits

5.1.3 Tool Selection

Tool selection is made by specifying the T code corresponding to the tool number. Refer to the machine tool builder's manual for the relationship between the tool selection number and the tool.

5.1.4 Offset Number

Tool offset number has two meanings. It specifies the offset distance corresponding to the number that is selected to begin the offset function. A tool offset number of 0 indicates that the offset amount is 0 and the offset is cancelled.
5.1.5 Offset

Explanation
- Offset methods

There are the following two methods available for tool geometry and wear compensation: Tool movement and coordinate shift methods. Either of these methods can be selected using bits 2 (LWT) and 4 (LGT) of parameter No. 5002. When tool geometry and wear compensation is disabled (bit 6 (NGW) of parameter No. 8136 is set to 1), however, compensation with tool movement is used unconditionally.

<table>
<thead>
<tr>
<th>Bit 6 (NGW) of No.8136</th>
<th>Compensation element</th>
<th>Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>LWT=0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>LGT=0</td>
</tr>
<tr>
<td>1</td>
<td>Wear and geometry not distinguished</td>
<td>Tool movement</td>
</tr>
<tr>
<td>0</td>
<td>Wear compensation</td>
<td>Tool movement</td>
</tr>
<tr>
<td></td>
<td>Geometry compensation</td>
<td>Coordinate shift</td>
</tr>
</tbody>
</table>

- Offset with tool movement

The tool path is offset by the X, Y, and Z tool offset values for the programmed path. The tool offset distance corresponding to the number specified by the T code is added to or subtracted from the end position of each programmed block.

The vector with tool offset X, Y, and Z is called the offset vector. Offset is the same as the offset vector.
NOTE

1. When G50 X_Z_T_ ; is specified, the tool is not moved. The coordinate system in which the coordinate value of the tool position is (X,Z) is set. The tool position is obtained by subtracting the offset value corresponding to the tool offset number specified in the T code.

2. The G codes in the 00 group other than G50 must not be specified in the same block as that containing a T code. If an invalid G code is specified, alarm PS0245 is issued.

- Offset with coordinate shift

The workpiece coordinate system is shifted by the X, Y, and Z tool offset amounts. Namely, the offset amount corresponding to the number designated with the T code is added to or subtracted from the absolute coordinates.

- Starting and canceling offset by specifying a T code

Specifying an tool offset number with a T code means to select the tool offset value corresponding to it and to start offset. Specifying 0 as a tool offset number means to cancel offset.

For offset with tool movement, whether to start or cancel the offset can be specified with parameter LWN (No. 5002#6). For compensation with coordinate shift, the offset is started and canceled when a T code is specified. For the cancellation of geometry compensation, its operation can be selected with LGC (No. 5002#5).

<table>
<thead>
<tr>
<th>Offset method</th>
<th>LWM (No.5002#6)=0</th>
<th>LWM (No.5002#6)=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tool movement</td>
<td>When a T code is specified</td>
<td>When an axial movement is specified</td>
</tr>
<tr>
<td>Coordinate shift</td>
<td>When a T code is specified (Note that geometry offset can be canceled only if LGC (No. 5002#5) = 1.)</td>
<td></td>
</tr>
</tbody>
</table>
- Canceling offset with reset

Tool offset is canceled under one of the following conditions:

<1> The power to the CNC is turned off and turned back on
<2> The reset button on the MDI unit is pressed
<3> A reset signal is input from the machine to the CNC

In cases <2> and <3> above, it is possible to select a cancel operation using parameters LVC (No. 5006#3) and TGC (No. 5003#7).

<table>
<thead>
<tr>
<th>Offset method</th>
<th>Parameter</th>
<th>LVC=0 TGC=0</th>
<th>LVC=1 TGC=0</th>
<th>LVC=0 TGC=1</th>
<th>LVC=1 TGC=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tool movement</td>
<td>Wear offset</td>
<td>x</td>
<td>o (When axial movement is specified)</td>
<td>x</td>
<td>o (When axial movement is specified)</td>
</tr>
<tr>
<td>Geometry offset</td>
<td>o</td>
<td>x</td>
<td>o</td>
<td>x</td>
<td>o</td>
</tr>
<tr>
<td>Coordinate shift</td>
<td>Wear offset</td>
<td>x</td>
<td>o</td>
<td>x</td>
<td>o</td>
</tr>
<tr>
<td>Geometry offset</td>
<td>x</td>
<td>x</td>
<td>o</td>
<td>o</td>
<td>o</td>
</tr>
</tbody>
</table>

o: Canceled.
x: Not canceled.

Example

N1 X60.0 Z50.0 T0202 ; Creates the offset vector corresponding to tool offset number 02.
N2 Z100.0 ;
N3 X200.0 Z150.0 T0200 ; Cancels the offset vector with offset number 0.
Limitation

- **Helical interpolation (G02, G03)**
  Tool offset cannot be specified in a block in which helical interpolation is used.

- **Workpiece coordinate system preset (G50.3)**
  Performing workpiece coordinate system preset causes tool offset with tool movement to be canceled; this does not cause tool offset with coordinate shift to be canceled.

- **Machine coordinate system setting (G53), reference position return (G28), second, third, and fourth reference position return (G30), and manual reference position return**
  Basically, before performing these commands or operations, cancel tool offset. These operations do not cause tool offset to be canceled.

  The following actions take place:

<table>
<thead>
<tr>
<th></th>
<th>When the command or operation is specified</th>
<th>When the next axial movement command is specified</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tool movement</td>
<td>The tool offset value is temporarily canceled.</td>
<td>The tool offset value is reflected.</td>
</tr>
<tr>
<td>Coordinate shift</td>
<td>Coordinates with the tool offset value reflected are assumed.</td>
<td>Coordinates with the tool offset value reflected are assumed.</td>
</tr>
</tbody>
</table>

### 5.1.6 Y Axis Offset

#### Overview

When the Y axis, one of the basic three axes, is used with a lathe system, this function performs Y axis offset.

When tool geometry and wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is set to 0), the compensation is also enabled for the Y axis offset.

#### Explanation

Y axis offset results in the same operation as tool offset. For an explanation of the operation, related parameters, and the like, refer to the item “Tool Offset.”

### 5.1.6.1 Y axis offset (arbitrary axes)

#### Overview

In a lathe system, Y axis offset has been usable with the basic three axes only. This function enables Y axis offset to be used with arbitrary axes other than the Y axis, which is one of the basic three axes. Specify an axis number for which to use Y axis offset for parameter No. 5043.
5.2 OVERVIEW OF TOOL NOSE RADIUS COMPENSATION (G40-G42)

It is difficult to produce the compensation necessary to form accurate parts when using only the tool offset function due to tool nose roundness in taper cutting or circular cutting. The tool nose radius compensation function compensates automatically for the above errors.

**NOTE**

To use tool nose radius compensation, set bit 7 (NCR) of parameter No. 8136 to 0.
5.2.1 Imaginary Tool Nose

The tool nose at position A in Fig. 5.2.1 (a) does not actually exist. The imaginary tool nose is required because it is usually more difficult to set the actual tool nose radius center to the start point than the imaginary tool nose. Also when imaginary tool nose is used, the tool nose radius need not be considered in programming. The position relationship when the tool is set to the start point is shown in Fig. 5.2.1 (a).

![Fig. 5.2.1 (a) Tool nose radius center and imaginary tool nose](image)
**CAUTION**

In a machine with reference positions, a standard position like the turret center can be placed over the start point. The distance from this standard position to the nose radius center or the imaginary tool nose is set as the tool offset value. Setting the distance from the standard position to the tool nose radius center as the offset value is the same as placing the tool nose radius center over the start point, while setting the distance from the standard position to the imaginary tool nose is the same as placing the imaginary tool nose over the standard position. To set the offset value, it is usually easier to measure the distance from the standard position to the imaginary tool nose than from the standard position to the tool nose radius center.

![Fig. 5.2.1 (b) Tool offset value when the turret center is placed over the start point](image)

Unless tool nose radius compensation is performed, the tool nose center path is the same as the programmed path. If tool nose radius compensation is used, accurate cutting will be performed.

![Fig. 5.2.1 (c) Tool path when programming using the tool nose center](image)

Without tool nose radius compensation, the tool nose radius center path is the same as the programmed path. With tool nose radius compensation, accurate cutting will be performed.

![Fig. 5.2.1 (d) Tool path when programming using the imaginary tool nose](image)
5.2.2 Direction of Imaginary Tool Nose

The direction of the imaginary tool nose viewed from the tool nose center is determined by the direction of the tool during cutting, so it must be set in advance as well as offset values.

The direction of the imaginary tool nose can be selected from the eight specifications shown in the Fig. 5.2.2 (a) below together with their corresponding codes. This Fig 5.2.2 (a) illustrates the relation between the tool and the start point. The following apply when the tool geometry offset and tool wear offset option are selected.

![Fig. 5.2.2 (a) Direction of imaginary tool nose](image-url)
Imaginary tool nose numbers 0 and 9 are used when the tool nose center coincides with the start point. Set imaginary tool nose number to address OFT for each offset number. Bit 7 (WNP) of parameter No. 5002 is used to determine whether the tool geometry offset number or the tool wear offset number specifies the direction of the virtual tool nose for tool nose radius compensation.

![ Imaginary tool nose number 0 or 9 ]
5.2.3 Offset Number and Offset Value

Explanation
- Offset number and offset value

When tool geometry and wear compensation is disabled (bit 6 (NGW) of parameter No. 8136 is set to 1), the following numbers and values are set:

<table>
<thead>
<tr>
<th>Offset number</th>
<th>OFX (Offset value on X axis)</th>
<th>OFZ (Offset value on Z axis)</th>
<th>OFR (Tool nose radius compensation value)</th>
<th>OFT (Direction of imaginary tool nose)</th>
<th>OFY (Offset value on Y axis)</th>
</tr>
</thead>
<tbody>
<tr>
<td>001</td>
<td>0.040</td>
<td>0.200</td>
<td>0.200</td>
<td>1</td>
<td>0.030</td>
</tr>
<tr>
<td>002</td>
<td>0.060</td>
<td>0.300</td>
<td>0.250</td>

- Tool nose radius compensation

When tool geometry and wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is set to 0), the total of the geometry and wear offset amounts is used as the tool nose radius compensation value during execution.

\[ \text{OFR} = \text{OFGR} + \text{OFWR} \]

- Imaginary tool nose direction

The imaginary tool nose direction is common to geometry and wear offsets.

- Command of offset value

A offset number is specified with the same T code as that used for tool offset.

**NOTE**

When the geometry offset number is made common to the tool selection by the parameter LGN (No.5002#1) setting and a T code for which the geometry offset and wear offset number differ from each other is designated, the imaginary tool nose direction specified by the geometry offset number is valid.

Example) T0102

\[ \text{OFR} = \text{OFGR}_{01} + \text{OFWR}_{02} \]
\[ \text{OFT} = \text{OFT}_{01} \]

By setting parameter WNP (No. 5002#7) appropriately, the imaginary tool nose direction specified with the wear offset number can be made valid.

- Setting range of offset value

The range of values that can be set as a compensation value is either of the following, depending on the bits 1 (OFC) and 0 (OFA) of parameter No. 5042).

**Valid compensation range (metric input)**

<table>
<thead>
<tr>
<th>OFC</th>
<th>OFA</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>±9999.99mm</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>±9999.999mm</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>±9999.9999mm</td>
</tr>
</tbody>
</table>

**Valid compensation range (inch input)**

<table>
<thead>
<tr>
<th>OFC</th>
<th>OFA</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>±999.999inch</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>±999.9999inch</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>±999.99999inch</td>
</tr>
</tbody>
</table>

The offset value corresponding to the offset number 0 is always 0. No offset value can be set to offset number 0.
5.2.4 Workpiece Position and Move Command

In tool nose radius compensation, the position of the workpiece with respect to the tool must be specified.

<table>
<thead>
<tr>
<th>G code</th>
<th>Workpiece position</th>
<th>Tool path</th>
</tr>
</thead>
<tbody>
<tr>
<td>G40</td>
<td>(Cancel)</td>
<td>Moving along the programmed path</td>
</tr>
<tr>
<td>G41</td>
<td>Right side</td>
<td>Moving on the left side the programmed path</td>
</tr>
<tr>
<td>G42</td>
<td>Left side</td>
<td>Moving on the right side the programmed path</td>
</tr>
</tbody>
</table>

The tool is offset to the opposite side of the workpiece.

Fig. 5.2.4 (a) Workpiece position
The workpiece position can be changed by setting the coordinate system as shown below.

G40, G41, and G42 are modal. Don't specify G41 while in the G41 mode. If you do, compensation will not work properly. Don't specify G42 while in the G42 mode for the same reason. G41 or G42 mode blocks in which G41 or G42 are not specified are expressed by (G41) or (G42) respectively.

⚠️ CAUTION
If the sign of the compensation value is changed from plus to minus and vice versa, the offset vector of tool nose radius compensation is reversed, but the direction of the imaginary tool tip does not change. For a use in which the imaginary tool tip is adjusted to the starting point, therefore, do not change the sign of the compensation value for the assumed program.
Explanation

- Tool movement when the workpiece position does not change
  When the tool is moving, the tool nose maintains contact with the workpiece.

- Tool movement when the workpiece position changes
  The workpiece position against the tool changes at the corner of the programmed path as shown in the following figure.

Although the workpiece does not exist on the right side of the programmed path in the above case, the existence of the workpiece is assumed in the movement from A to B. The workpiece position must not be changed in the block next to the start-up block. In the above example, if the block specifying motion from A to B were the start-up block, the tool path would not be the same as the one shown.
- Start-up

The block in which the mode changes to G41 or G42 from G40 is called the start-up block.

G40 ;
G41 ; (Start-up block)

Transient tool movements for offset are performed in the start-up block. In the block after the start-up block, the tool nose center is positioned vertically to the programmed path of that block at the start point.

![Fig. 5.2.4 (e) Start-up](image)

- Offset cancel

The block in which the mode changes to G40 from G41 or G42 is called the offset cancel block.

G41 ;
G40 ; (Offset cancel block)

The tool nose center moves to a position vertical to the programmed path in the block before the cancel block. The tool is positioned at the end position in the offset cancel block (G40) as shown below.

![Fig. 5.2.4 (f) Offset cancel](image)
- Changing the compensation value

In general, the compensation value is to be changed when the tool is changed in offset cancel mode. If the compensation value is changed in offset mode, however, the vector at the end point of the block is calculated using the compensation value specified in that same block. The same applies if the imaginary tool nose direction and the tool offset value are changed.

![Diagram showing compensation value](image)

**Fig. 5.2.4 (g) Changing the compensation value**

- Specification of G41/G42 in G41/G42 mode

When a G41 or G42 code is specified again in G41/G42 mode, the tool nose center is positioned vertical to the programmed path of the preceding block at the end position of the preceding block.

![Diagram showing G41/G42 positioning](image)

**Fig. 5.2.4 (h) Specification of G41/G42 in G41/G42 mode**

In the block that first changes from G40 to G41/G42, the above positioning of the tool nose center is not performed.
- Tool movement when the moving direction of the tool in a block which includes a G40 (offset cancel) command is different from the direction of the workpiece

When you wish to retract the tool in the direction specified by X(U) and Z(W) canceling the tool nose radius compensation at the end of machining the first block in the figure below, specify the following:

\[ G40 \ X(U) \ Z(W) \ I \ K ; \]

where I and K are the direction of the workpiece in the next block, which is specified in incremental mode.

![Diagram of tool movement and G40](image)

**Fig. 5.2.4 (i) If I and K are specified in the same block as G40**

Thus, this prevents the tool from overcutting, as shown in Fig. 5.2.4 (j).

![Diagram of overcutting and G40](image)

**Fig. 5.2.4 (j) Case in which overcutting occurs in the same block as G40**

The workpiece position specified by addresses I and K is the same as that in the preceding block.

Specify I_K; in the same block as G40. If it is specified in the same block as G02 or G03, it is assumed to be the center of the arc.

| G40 X_ Z_ I_ K_ ;               | Tool nose radius compensation |
| G02 X_ Z_ I_ K_ ;               | Circular interpolation        |

If I and/or K is specified with G40 in the offset cancel mode, the I and/or K is ignored. The numeral is followed I and K should always be specified as radius values.

G40 G01 X_ Z_ ;
G40 G01 X_ Z_ I_ K_ ; Offset cancel mode (I and K are ineffective.)
Example

(G40 mode)
<1> G42 G00 X60.0 ;
<2> G01 X120.0 W-150.0 F10 ;
<3> G40 G00 X300.0 W150.0 I40.0 K-30.0 ;
5.2.5 Notes on Tool Nose Radius Compensation

Explanation
- Blocks without a move command that are specified in offset mode

- G code only

If the number of such blocks consecutively specified is more than N-2 blocks (where N is the number of blocks to read in offset mode (parameter No. 19625)), the tool arrives at the position vertical to this block at the end point of the previous block.

If the feed distance is 0 (<5>), this applies even if only one block is specified.

- Tool nose radius compensation with G90 or G94

The tool nose center path and the offset direction are as shown below if tool nose radius compensation is applied. At the cycle start point, the offset vector disappears, and offset starts up with tool movement from the cycle start point. In addition, during a return to the cycle start point, the offset vector disappears temporarily, and offset is applied again with the next move command. The offset direction is determined by the cutting pattern, regardless of G41 or G42.
- Outer/inner turning cycle (G90)

![Diagram of Tool nose radius center path and Offset direction for Outer/inner turning cycle (G90)]

- End cutting cycle (G94)

![Diagram of Tool nose radius center path and Offset direction for End cutting cycle (G94)]

- Difference from Series 0i-C

**NOTE**

The offset direction is the same as that of Series 0i-C, but the tool nose radius center path is different.

- For this CNC
  The operation is the same as that performed if the canned cycle operation is replaced with G00 or G01, start-up is performed in the first block for movement from the start point, and offset cancel is performed in the last block for returning to the start point.

- For Series 0i-C
  The operation with the block for movement from the start point and the last block for returning to the start point differs from that of this CNC. For details, refer to the Series 0i-C Operator's Manual.
- **Tool nose radius compensation with G71 to G73**
  Tool nose radius compensation performed with G71 (outer surface rough cutting cycle or traverse grinding cycle), G72 (end rough cutting cycle or traverse direct constant-size grinding cycle), and G73 (closed loop cutting cycle or oscillation direct constant-size grinding cycle), see the explanations of the respective cycles.

- **Tool nose radius compensation with G74 to G76 and G92**
  With G74 (end cutting off cycle), G75 (outer/inner surface cutting off cycle), G76 (multiple threading cycle), and G92 (threading cycle), tool nose radius compensation cannot be applied.

- **Tool nose radius compensation when chamfering is performed**
  Movement after compensation is shown below.

```
(G42 mode)
G01 W-20.0 I10.0;
U20.0;
```

- **Tool nose radius compensation when a corner arc is inserted**
  Movement after compensation is shown below.

```
(G42 mode)
G01 W-20.0 R10.0;
U20.0;
```

- **Tool nose radius compensation for MDI operation.**
  Tool nose radius compensation is valid for MDI operation.

**NOTE**
For Series 0i-C, tool nose radius compensation is invalid for MDI operation.
5.3 DETAILS OF TOOL NOSE RADIUS COMPENSATION

5.3.1 Overview

This subsection details tool movement in tool nose radius compensation.

- Tool nose radius center offset vector

The tool nose radius center offset vector is a two dimensional vector equal to the offset value specified in a T code, and the vector is calculated in the CNC. Its dimension changes block by block according to tool movement.

This offset vector (simply called vector herein after) is internally crated by the control unit as required for proper offsetting and to calculate a tool path with exact offset (by tool nose radius) from the programmed path.

This vector is deleted by resetting.

The vector always accompanies the tool as the tool advances.

Proper understanding of vector is essential to accurate programming.

Read the description below on how vectors are created carefully.

- G40, G41, G42

G40, G41 or G42 is used to delete or generate vectors.

These codes are used together with G00, G01, G02, or G32 to specify a mode for tool motion (Offsetting).

<table>
<thead>
<tr>
<th>G code</th>
<th>Workpiece position</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>G40</td>
<td>Neither</td>
<td>Tool nose radius compensation cancel</td>
</tr>
<tr>
<td>G41</td>
<td>Right</td>
<td>Left offset along tool path</td>
</tr>
<tr>
<td>G42</td>
<td>Left</td>
<td>Right offset along tool path</td>
</tr>
</tbody>
</table>

G41 and G42 specify an offset mode, while G40 specifies cancellation of the offset.

- Inner side and outer side

When an angle of intersection of the tool paths specified with move commands for two blocks on the workpiece side is over 180°, it is referred to as "inner side." When the angle is between 0° and 180°, it is referred to as "outer side."
- Outer corner connection method

If the tool moves around an outer corner in tool nose radius compensation mode, it is possible to specify whether to connect compensation vectors with linear interpolation or with circular interpolation, using parameter CCC (No. 19607#2).

1. Linear connection type
   [Parameter CCC (No.19607#2) = 0]
   Vectors are connected with linear interpolation.

2. Circular connection type
   [Parameter CCC (No.19607#2) = 1]
   Vectors are connected with circular interpolation.

- Cancel mode

The tool nose radius compensation enters the cancel mode under the following conditions. (The system may not enter the cancel mode depending on the machine tool.)

1. Immediately after the power is turned on
2. After the key on the MDI panel is pushed
3. After a program is forced to end by executing M02 or M30
4. After the tool nose radius compensation cancel command (G40) is exercised

In the cancel mode, the magnitude of a compensation vector is 0 at all times and the path of the virtual tool nose matches the programmed path. A program must end in cancel mode. If it ends in the tool nose radius compensation mode, the tool cannot be positioned at the end point, and the tool stops at a location the compensation vector length away from the end point.
### NOTE

The operation performed when a reset operation is performed during tool nose radius compensation varies according to the setting of bit 6 (CLR) of parameter No. 3402.

- **When CLR=0**
  - The reset state is set. The modal information of G41/G42 in group 07 is preserved. To perform tool nose radius compensation, however, an offset number (T code) needs to be specified again.

- **When CLR=1**
  - The cleared state is set. The modal information of G40 in group 07 is preserved. To perform tool nose radius compensation, G41/G42 and an offset number (T code) need to be specified.

### - Start-up

When a block which satisfies all the following conditions is executed in cancel mode, the CNC enters the offset mode. Control during this operation is called start-up.

1. G41 or G42 is contained in the block, or has been specified to place the CNC in the offset mode.
2. \(0 < \text{compensation number of tool nose radius compensation} \leq \text{maximum compensation number}\)
3. Positioning (G00) or linear interpolation (G01) mode
4. A compensation plane axis command with a travel distance of 0 (except start-up type C) is specified.

If start-up is specified in circular interpolation (G02, G03) mode, alarm PS0034 will occur.

As a start-up operation, one of the three types A, B, and C can be selected by setting bits 0 (SUP) and 1 (SUV) of parameter No. 5003 appropriately. The operation to be performed if the tool moves around an inner side is of single type only.
### Table 5.3.1 (a) Start-up/cancel operation

<table>
<thead>
<tr>
<th>SUV</th>
<th>SUP</th>
<th>Type</th>
<th>Operation</th>

</tr>
<tr>
<td></td>
<td>1</td>
<td></td>
<td><img src="" alt="Diagram" /></td>
</tr>
</tbody>
</table>

For a block with tool movement, the tool follows the SUP setting: If it is 0, type A is assumed and if 1, type B is assumed.
- Reading input commands in tool nose radius compensation mode

In tool nose radius compensation mode, input commands are read from usually three blocks and up to eight blocks depending on the setting of parameter (No. 19625) to perform intersection calculation or an interference check, described later, regardless of whether the blocks are with or without tool movement, until a cancel command is received.

To perform intersection calculation, it is necessary to read at least two blocks with tool movement. To perform an interference check, it is necessary to read at least three blocks with tool movement.

As the setting of parameter (No. 19625), that is, the number of blocks to read, increases, it is possible to predict overcutting (interference) for up to more subsequent commands. Increases in blocks to read and analyze, however, cause reading and analysis to take more time.

- Meaning of symbols

The following symbols are used in subsequent figures:
- S indicates a position at which a single block is executed once.
- SS indicates a position at which a single block is executed twice.
- SSS indicates a position at which a single block is executed three times.
- L indicates that the tool moves along a straight line.
- C indicates that the tool moves along an arc.
- r indicates the tool nose radius compensation value.
- An intersection is a position at which the programmed paths of two blocks intersect with each other after they are shifted by r.
- Indicates the center of the tool nose radius.
5.3.2 Tool Movement in Start-up

When the offset cancel mode is changed to offset mode, the tool moves as illustrated below (start-up):

**Explanation**

- Tool movement around an inner side of a corner \((180^\circ \leq \alpha)\)
- Cases in which the start-up block is a block with tool movement and the tool moves around the outside at an obtuse angle (90° ≤ α < 180°)

Tool path in start-up has two types A and B, and they are selected by parameter SUP (No.5003#0).
There are two types of compensation function programming mentioned:

1. **Linear → Linear (Circular connection type)**
   - Start point: \( L \)
   - Tool nose radius: \( r \)
   - Center path: \( C \)
   - Workpiece
   - Programmed path

2. **Linear → Circular (Circular connection type)**
   - Start point: \( G42 \)
   - Tool nose radius: \( r \)
   - Center path: \( C \)
   - Workpiece
   - Programmed path

The diagrams illustrate the paths and connections for each type, showing how the tool moves from one point to another with consideration for the radius and center.
- Cases in which the start-up block is a block with tool movement and the tool moves around the outside at an acute angle ($\alpha<90^\circ$)

Tool path in start-up has two types A and B, and they are selected by parameter SUP (No.5003#0).
- Tool movement around the outside linear → linear at an acute angle less than 1 degree (α<1°)

- A block without tool movement specified at start-up

For type A and B
If the command is specified at start-up, the offset vector is not created. The tool does not operate in a start-up block.

G40 ... ;
N6 U100.0 W100.0 ;
N7 G41 U0 ;
N8 U-100.0 ;
N9 U-100.0 W100.0 ;
For type C
The tool shifts by the compensation value in the direction vertical to the block with tool movement subsequent to the start-up block.
5.3.3 Tool Movement in Offset Mode

In offset mode, compensation is performed even for positioning commands, not to speak of linear and circular interpolations. To perform intersection calculation, it is necessary to read at least two blocks with tool movement. If, therefore, two or more blocks with tool movement cannot be read in offset mode because blocks without tool movement, such as auxiliary function independent commands and dwell, are specified in succession, excessive or insufficient cutting may occur because intersection calculation fails. Assuming the number of blocks to read in offset mode, which is determined by parameter (No. 19625), to be N and the number of commands in those N blocks without tool movement that have been read to be M, the condition under which intersection calculation is possible is \((N - 2) \geq M\). For example, if the maximum number of blocks to read in offset mode is 5, intersection calculation is possible even if up to three blocks without tool movement are specified.

**NOTE**

The condition necessary for an interference check, described later, differs from this condition. For details, see the explanation of the interference check.

If a G or M code in which buffering is suppressed is specified, no subsequent commands can be read before that block is executed, regardless of the setting of parameter (No. 19625). Excessive or insufficient cutting may, therefore, occur because of an intersection calculation failure.
- Tool movement around the inside of a corner \((180^\circ \leq \alpha)\)
- Tool movement around the inside (α<1°) with an abnormally long vector, linear → linear

![Diagram showing tool movement and intersections](image)

Also in case of arc to straight line, straight line to arc and arc to arc, the reader should infer in the same procedure.
- Tool movement around the outside corner at an obtuse angle (90° ≤ α < 180°)

Linear → Linear (Linear connection type)

Linear → Circular (Linear connection type)

Circular → Linear (Linear connection type)

Circular → Circular (Linear connection type)
5. COMPENSATION FUNCTION PROGRAMMING

- Linear → Linear (Circular connection type)
- Linear → Circular (Circular connection type)
- Circular → Linear (Circular connection type)
- Circular → Circular (Circular connection type)
- Tool movement around the outside corner at an acute angle ($\alpha<90^\circ$)

Linear $\rightarrow$ Linear (Linear connection type)

Linear $\rightarrow$ Circular (Linear connection type)

Circular $\rightarrow$ Linear (Linear connection type)

Circular $\rightarrow$ Circular (Linear connection type)
- When it is exceptional
  End position for the arc is not on the arc

If the end of a line leading to an arc is not on the arc as illustrated below, the system assumes that the tool nose radius compensation has been executed with respect to an imaginary circle that has the same center as the arc and passes the specified end position. Based on this assumption, the system creates a vector and carries out compensation. The same description applies to tool movement between two circular paths.

There is no inner intersection

If the tool nose radius compensation value is sufficiently small, the two circular tool center paths made after compensation intersect at a position (P). Intersection P may not occur if an excessively large value is specified for tool nose radius compensation. When this is predicted, alarm PS0033 occurs at the end of the previous block and the tool is stopped.

In the example shown below, tool center paths along arcs A and B intersect at P when a sufficiently small value is specified for tool nose radius compensation. If an excessively large value is specified, this intersection does not occur.
- When the center of the arc is identical with the start point or the end position

If the center of the arc is identical with the start point or end point, alarm PS0041 is displayed, and the tool will stop at the start point of the preceding block of the arc.

```
N5
G01 W50.0 ;
N6 W50.0 ;
N7 G02 W100.0 I0 K0 ;
N8 G01 U-100.0 ;
```

- Change in the offset direction in the offset mode

The offset direction is decided by G codes (G41 and G42) for tool nose radius compensation and the sign of the compensation value as follows.

<table>
<thead>
<tr>
<th>G code</th>
<th>Sign of compensation</th>
<th>+</th>
<th>-</th>
</tr>
</thead>
<tbody>
<tr>
<td>G41</td>
<td>Left side offset</td>
<td>Right side offset</td>
<td></td>
</tr>
<tr>
<td>G42</td>
<td>Right side offset</td>
<td>Left side offset</td>
<td></td>
</tr>
</tbody>
</table>

The offset direction can be changed in the offset mode. If the offset direction is changed in a block, a vector is generated at the intersection of the tool nose radius center path of that block and the tool nose radius center path of a preceding block. However, the change is not available in the start-up block and the block following it.
- Tool nose radius center path with an intersection

**Linear → Linear**

**Linear → Circular**

**Circular → Linear**

**Circular → Circular**
- Tool nose radius center path without an intersection

When changing the offset direction in block A to block B using G41 and G42, if intersection with the offset path is not required, the vector normal to block B is created at the start point of block B.
The length of tool center path larger than the circumference of a circle

Normally there is almost no possibility of generating this situation. However, when G41 and G42 are changed, or when a G40 was commanded with address I, J, and K this situation can occur.

In this case of the figure, the cutter compensation is not performed with more than one circle circumference: an arc is formed from P1 to P2 as shown. Depending on the circumstances, an alarm may be displayed due to the "Interference Check" described later. To execute a circle with more than one circumference, the circle must be specified in segments.

(G42)
N5 G01 U-700.0 W500.0 ;
N6 G41 G02 I-500.0 ;
N7 G42 G01 U700.0 W500.0 ;
- Tool nose radius compensation G code in the offset mode

The offset vector can be set to form a right angle to the moving direction in the previous block, irrespective of machining inner or outer side, by commanding the tool nose radius compensation G code (G41, G42) in the offset mode, independently. If this code is specified in a circular command, correct circular motion will not be obtained.

When the direction of offset is expected to be changed by the command of tool nose radius compensation G code (G41, G42), see "Change in the offset direction in the offset mode".

![Diagram of linear to linear tool nose radius compensation](image)

![Diagram of circular to linear tool nose radius compensation](image)
- Command canceling the offset vector temporarily

During offset mode, if G50 (workpiece coordinate system setting) or G52 (local coordinate system setting) is commanded, the offset vector is temporarily cancelled and thereafter offset mode is automatically restored.

In this case, without movement of offset cancel, the tool moves directly from the intersecting point to the commanded point where offset vector is canceled.

Also when restored to offset mode, the tool moves directly to the intersecting point.

Before specifying G28 (reference position return), G30 (second, third, and fourth reference position returns), and G53 (machine coordinate system selection) commands, cancel offset mode, using G40. If an attempt is made to specify any of the commands in offset mode, the offset vector temporarily disappears.

- Canned cycles (G90, G92, G94) and multiple repetitive canned cycles (G71 to G76)

See the cautions for the tool nose radius compensation related canned cycles.
- If I, J, and K are specified in a G00/G01 mode block

At the start of tool nose radius compensation or in that mode, by specifying I, J, and K in a positioning mode (G00) or linear interpolation mode (G01) block, it is possible to set the compensation vector at the end point of that block in the direction vertical to that specified by I, J, and K. This makes it possible to change the compensation direction intentionally.

IJ type vector (XY plane)

The following explains the compensation vector (IJ type vector) to be created on the XY compensation plane (G17 mode). (The same explanation applies to the KI type vector on the G18 plane and the JK type vector on the G19 plane.) As shown in the figure below, it is assumed that the compensation vector (IJ type vector) is the vector with a size equal to the compensation value and vertical to the direction specified by I and J, without performing intersection calculation on the programmed path. I and J can be specified both at the start of tool nose radius compensation and in that mode. If they are specified at the start of compensation, any start-up type set in the appropriate parameter will be invalid, and an IJ type vector is assumed.

Offset vector direction

In G41 mode, the direction specified by I, J, and K is assumed an imaginary tool movement direction, and an offset vector is created vertical to that direction and on the left side.

In G42 mode, the direction specified by I, J, and K is assumed an imaginary tool movement direction, and an offset vector is created vertical to that direction and on the right side.
Example

If I and J are specified at the start of compensation (with tool movement)

\[
\begin{align*}
\text{(G40)} & \\
N10 & \text{G41 U100.0 W100.0 K1 T0101 ;} \\
N20 & \text{G04 X1000 ;} \\
N30 & \text{G01 F1000 ;} \\
N40 & \text{S300 ;} \\
N50 & \text{M50 ;} \\
N60 & \text{W150. ;}
\end{align*}
\]

Note) In N10, a vector is specified with a size of T1 in the direction vertical to the Z axis, using K1.

If I and J are specified at the start of compensation (without tool movement)

\[
\begin{align*}
\text{(G40)} & \\
N10 & \text{G41 K1 T0101 ;} \\
N20 & \text{U100.0 W100.0 ;} \\
N30 & \text{W150.0 ;}
\end{align*}
\]

Note) In N10, a vector is specified with a size of T1 in the direction vertical to the Z axis, using K1.

If I and J are specified at the start of compensation (with tool movement)

\[
\begin{align*}
\text{(G17 G41 T0101)} & \\
N10 & \text{G00 U150.0 J50.0 ;} \\
N20 & \text{G02 I50.0 ;} \\
N30 & \text{G00 U-150.0 ;}
\end{align*}
\]

Note) In N10, a vector is specified with a size of T1 in the direction vertical to the Y axis, using J50.

<1> IJ type vector
<2> Vector determined with intersection calculation

<1> IJ type vector
<2> Vector determined with intersection calculation
Limitation

If an IJ type vector is specified, tool interference may occur due to that vector alone, depending on the direction. If this occurs, no interference alarm will occur, or no interference avoidance will be performed. Overcutting may, therefore, result.

- A block without tool movement

The following blocks have no tool movement. In these blocks, the tool will not move even if cutter compensation is effected.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
- A block without tool movement specified in offset mode

Unless the number of blocks without movement consecutively specified is more than N-2 blocks (where N is the number of blocks to read in offset mode (parameter No. 19625)) in offset mode, the vector and the tool nose radius center path will be as usual. This block is executed at the single block stop point.

```
N6 U100.0 W100.0;
N7 G04 X10.0;
N8 W100.0;
```

For an axis command for which the move distance is zero, however, a vector with a size equal to the compensation value will be created vertical to the movement direction in the previous block, even if the number of block is 1. Note that specifying such a command may result in overcutting.

```
N6 U100.0 W100.0;
N7 U0;
N8 W100.0;
```

In offset mode, the number of blocks without movement consecutively specified must not exceed N-2 (where N is the number of blocks to read in offset mode (parameter (No. 19625)). If commanded, a vector whose length is equal to the offset value is produced in a normal direction to tool motion in earlier block, so overcutting may result.

```
N6 U100.0 W100.0;
N7 S21;
N8 G04 X10.0;
N9 W100.0;
(No. of blocks to read in offset mode = 3)
```

If an M/G code that suppresses buffering is specified

If an M/G code that suppresses buffering is specified in offset mode, it is no longer possible to read and analyze subsequent blocks regardless of the number of blocks to read in offset mode, which is determined by parameter (No. 19625). Then, intersection calculation and an interference check, described later, are no longer possible. If this occurs, overcutting may occur because a vertical vector is output in the immediately preceding block.

If an M code (M50) that suppresses buffering is not specified

```plaintext
(G42)
N5 G01 U40.0 W40.0 ;
N6 W40.0 ;

N5

N6 M50 ;
N7 W40.0 ;

N5

SS

Block N6 is executed here.

N6

N7

Programmed path

Tool nose radius center path
```
- Corner movement

When two or more offset vectors are produced at the end of a block, the tool moves linearly from one vector to another. This movement is called the corner movement. If these vectors almost coincide with each other (the distance of corner movement between the vectors is judged short due to the setting of parameter (No. 5010)), corner movement is not performed. In this case, the vector to the single block stop point takes precedence and remains, while other vectors are ignored. This makes it possible to ignore the very small movements arising from performing tool nose radius compensation, thereby preventing velocity changes due to interruption of buffering.

\[ \Delta V_{\text{limit}} \]

\[ \Delta V_X \leq \Delta V_{\text{limit}} \text{ and } \Delta V_Z \leq \Delta V_{\text{limit}} \]

If the vectors are not judged to almost coincide (therefore, are not erased), movement to turn around the corner is performed. The corner movement that precedes the single block stop point belongs to the previous block, while the corner movement that succeeds the single block stop point belongs to the latter block.
However, if the path of the next block is semicircular or more, the above function is not performed. The reason for this is as follows:

If the vector is not ignored, the tool path is as follows:

\[
P_1 \rightarrow P_2 \rightarrow P_3 \rightarrow \text{(Circle)} \rightarrow P_4 \rightarrow P_5 \rightarrow P_6
\]

But if the distance between \( P_2 \) and \( P_3 \) is negligible, the point \( P_3 \) is ignored. Therefore, the tool path is as follows:

\[
P_2 \rightarrow P_4
\]

Namely, circle cutting by the block \( N_6 \) is ignored.

- **Interruption of manual operation**

For manual operation during the offset mode, see "Manual Absolute ON and OFF."
5.3.4 Tool Movement in Offset Mode Cancel

Explanation
- If the cancel block is a block with tool movement, and the tool moves around the inside (180° ≤ α)

- Linear→Linear

- Circular→Linear
- If the cancel block is a block with tool movement, and the tool moves around the outside at an obtuse angle \((90^\circ \leq \alpha < 180^\circ)\)

The two types, A and B, are available. Set bit 0 (SUP) of parameter No. 5003 to specify which type is to be used.
Type B

Linear → Linear
(Circular connection type)

Circular → Linear
(Circular connection type)
- If the cancel block is a block with tool movement, and the tool moves around the outside at an acute angle ($\alpha<90^\circ$)

The two types, A and B, are available. Set bit 0 (SUP) of parameter No. 5003 to specify which type is to be used.

</table>
- If the cancel block is a block with tool movement, and the tool moves around the outside at an acute angle of 1 degree or less in a linear → linear manner (\(\alpha \leq 1^\circ\))

- A block without tool movement specified together with offset cancel
  For types A and B
  In the block preceding the cancel block, a vector is created with a size equal to the tool nose radius compensation value in the vertical direction. The tool does not operate in the cancel block. The remaining vectors are canceled with the next move command.
For type C
The tool shifts by the compensation value in the direction vertical to the block preceding the cancel block.

- Block containing G40 and I_, J_, K_
  The previous block contains G41 or G42

If a G41 or G42 block precedes a block in which G40 and I_, J_, K_ are specified, the system assumes that the path is programmed as a path from the end position determined by the former block to a vector determined by (I,J), (I,K), or (J,K). The direction of compensation in the former block is inherited.

In this case, note that the CNC obtains an intersection of the tool path irrespective of whether inner or outer side machining is specified.
When an intersection is not obtainable, the tool comes to the normal position to the previous block at the end of the previous block.

- Length of the tool center path larger than the circumference of a circle
In the example shown below, the tool does not trace the circle more than once. It moves along the arc from P₁ to P₂. The interference check function described below may raise an alarm. To make the tool trace a circle more than once, program two or more arcs.
5.3.5 Prevention of Overcutting Due to Tool Nose Radius Compensation

Explanation
- Machining a groove smaller than the diameter of the tool nose

Since the tool nose radius compensation forces the path of the center of the tool nose radius to move in the reverse of the programmed direction, overcutting will result. In this case an alarm is displayed and the CNC stops at the start of the block.

![Diagram showing prevention of overcutting due to tool nose radius compensation](image)

Fig. 5.3.5 (a) Machining a groove smaller than the diameter of the tool nose
- Machining a step smaller than the tool nose radius

For a figure in which a workpiece step is specified with an arc, the tool nose radius center path will be as shown in Fig. 5.3.5 (b). If the step is smaller than the tool nose radius, the tool nose radius center path usually compensated as shown in Fig. 5.3.5 (c) may be in the direction opposite to the programmed path. In this case, the first vector is ignored, and the tool moves linearly to the second vector position. The single block operation is stopped at this point. If the machining is not in the single block mode, the cycle operation is continued.

If the step is of linear, no alarm will be generated and cut correctly. However uncut part will remain.

![Fig. 5.3.5 (b) Machining a step larger than the tool nose radius](image)

![Fig. 5.3.5 (c) Machining a step smaller than the tool nose radius](image)
Starting compensation and cutting along the Z-axis

It is usually used such a method that the tool is moved along the Z axis after the tool nose radius compensation (normally XY plane) is effected at some distance from the workpiece at the start of the machining. In the case above, if it is desired to divide the motion along the Z axis into rapid traverse and cutting feed, follow the procedure below.

Let us consider the following program, assuming the number of blocks to read in tool nose radius compensation mode (parameter (No. 19625)) to be 3.

```
N1 G00 G41 U500.0 V500.0 T0101;
N3 G01 W-300.0 F100;
N6 V1000.0 F200;
```

In the program example above, when executing block N1, blocks N3 and N6 are also entered into the buffer storage, and by the relationship among them the correct compensation is performed as in the figure above.

Then, suppose that the block N3 (move command in Z axis) is divided into N3 and N5.

```
N1 G00 G41 U500.0 V500.0 T0101;
N3 G01 W-250.0;
N5 G01 W-50.0 F100;
N6 V1000.0 F200;
```

At this time, because the number of blocks to read is 3, blocks up to N5 can be read at the start of N1 compensation, but block N6 cannot be read. As a result, compensation is performed only on the basis of the information in block N1, and a vertical vector is created at the end of the compensation start block. Usually, therefore, overcutting will result as shown in the figure above.
In such a case, it is possible to prevent overcutting by specifying a command with the exactly the same direction as the advance direction immediately before movement along the Z axis beforehand, after the tool is moved along the Z axis using the above rule.

As the block N2 has the move command in the same direction as that of the block N6, the correct compensation is performed.

Alternatively, it is possible to prevent overcutting in the same way by specifying an IJ type vector with the same direction as the advance direction in the start-up block, as in N1 G00 G41 U500.0 V500.0 I0 J1 T0101; after the tool has moved along the Z axis.
5.3.6 Interference Check

Tool overcutting is called interference. The interference check function checks for tool overcutting in advance. However, all interference cannot be checked by this function. The interference check is performed even if overcutting does not occur.

Explanation

- Condition under which an interference check is possible

To perform an interference check, it is necessary to read at least three blocks with tool movement. If, therefore, three or more blocks with tool movement cannot be read in offset mode because blocks without tool movement, such as independent auxiliary function and dwell, are specified in succession, excessive or insufficient cutting may occur because an interference check fails. Assuming the number of blocks to read in offset mode, which is determined by parameter (No. 19625), to be \( N \) and the number of commands in those \( N \) blocks without tool movement that have been read to be \( M \), the condition under which an interference check is possible is

\[
(N - 3) \geq M.
\]

For example, if the maximum number of blocks to read in offset mode is 8, an interference check is possible even if up to five blocks without tool movement are specified. In this case, three adjacent blocks can be checked for interference, but any subsequent interference that may occur cannot be detected.

- Interference check method

Two interference check methods are available, direction check and circular angle check. Parameter CNC (No. 5008#1) and parameter CNV (No. 5008#3) are used to specify whether to enable these methods.

<table>
<thead>
<tr>
<th>CNV</th>
<th>CNC</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>An interference check is enabled, and a direction check and a circular angle check can be performed.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>An interference check is enabled, and only a circular angle check is performed.</td>
</tr>
<tr>
<td>1</td>
<td>–</td>
<td>An interference check is disabled.</td>
</tr>
</tbody>
</table>

NOTE

There are no settings for performing a direction check only.
- Interference reference <1> (direction check)

Assuming the number of blocks to read during tool nose radius compensation to be N, a check is first performed on the compensation vector group calculated in (block 1 - block 2) to be output this time and the compensation vector group calculated in (block N-1 - block N); if they intersect, they are judged to interfere. If no interference is found, a check is performed sequentially in the direction toward the compensation vector group to be output this time, as follows:

(Block 1 - block 2) and (block N-2 - block N-1)
(Block 1 - block 2) and (block N-3 - block N-2)
  :
  :
(Block 1 - block 2) and (block 2 - block 3)

Even if multiple number of compensation vector groups are generated, a check is performed on all pairs.

The judgment method is as follows: For a check on the compensation vector group in (block 1 - block 2) and those in (block N-1 - block N), the direction vector from the specified (end point of block 1) to the (end point of block N-1) is compared with the direction vector from the (point resulting from adding the compensation vector to be checked to the end of block 1) to the (point resulting from adding the compensation vector to be checked to the end of block N-1), and if the direction is 90° or greater or 270° or less, they are judged to intersect and interfere. This is called a direction check.

Example of interference standard <1>
(If the block 1 end-point vector intersects with the block 7 end-point vector)
Example of interference standard <1>
(If the block 1 end-point vector intersects with the block 2 end-point vector)

![Diagram showing interference standard <1>](image)

- Interference reference <2> (circular angle check)

In a check on three adjacent blocks, that is, a check on the compensation vector group calculated on (block 1 - block 2) and the compensation vector group calculated on (block 2 - block 3), if block 2 is circular, a check is performed on the circular angle between the start and end points of the programmed path and the circular angle of the start and end point of the post-compensation path, in addition to direction check <1>. If the difference is 180° or greater, the blocks are judged to interfere. This is called a circular angle check.

Example of <2> (if block 2 is circular and the start point of the post-compensation arc coincide with the end point)

![Diagram showing interference reference <2>](image)
- **When interference is assumed although actual interference does not occur**

  <1> Depression which is smaller than the tool nose radius compensation value

  There is no actual interference, but since the direction programmed in block B is opposite to that of the path after the tool nose radius compensation, the tool stops and an alarm is displayed.

  <2> Groove which is smaller than the tool nose radius compensation value

  Like <1>, an alarm is displayed because of the interference as the direction is reverse in block B.
5.3.6.1 Operation to be performed if an interference is judged to occur

Explanation

The operation to be performed if an interference check judges that an interference (due to overcutting) occurs can be either of the following two, depending on the setting of parameter CAV (No. 19607#5).

<table>
<thead>
<tr>
<th>CAV</th>
<th>Function</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interference check alarm function</td>
<td>An alarm stop occurs before the execution of the block in which overcutting (interference) occurs.</td>
</tr>
<tr>
<td>1</td>
<td>Interference check avoidance function</td>
<td>The tool path is changed so that overcutting (interference) does not occur, and processing continues.</td>
</tr>
</tbody>
</table>

5.3.6.2 Interference check alarm function

Explanation

- Interference other than those between adjacent three blocks

If the end-point vector of block 1 and the end-point vector of block 7 are judged to interfere as shown in the figure, an alarm will occur before the execution of block 1 so that the tool stops. In this case, the vectors will not be erased.

![Interference Diagram]
- Interference between adjacent three blocks

If an interference is judged to occur between adjacent three blocks, the interfering vector, as well as any vectors existing inside of it, is erased, and a path is created to connect the remaining vectors. In the example shown in the figure below, V₂ and V₅ interfere, so that V₂ and V₅ are erased, so are V₃ and V₄, which are inside of them, and V₆ is connected to V₆. The operation during this time is linear interpolation.

If, after vector erasure, the last single vector still interferes, or if there is only one vector at the beginning and it interferes, an alarm will occur immediately after the start of the previous block (end point for a single block) and the tool stops. In the example shown in the figure below, V₂ and V₃ interfere, but, even after erasure, an alarm will occur because the final vectors V₁ and V₄ interfere.
5.3.6.3 Interference check avoidance function

Overview

If a command is specified which satisfies the condition under which the interference check alarm function generates an interference alarm, this function suppresses the generation of the interference alarm, but causes a new compensation vector to be calculated as a path for avoiding interference, thereby continuing machining. For the path for avoiding interference, insufficient cutting occurs in comparison with the programmed path. In addition, depending on the specified figure, no path for avoiding interference can be determined or the path for avoiding interference may be judged dangerous. In such a case, an alarm stop will occur. For this reason, it is not always possible to avoid interference for all commands.

Explanation

- Interference avoidance method

Let us consider a case in which an interference occurs between the compensation vector between (block 1 - block 2) and the compensation vector between (block N-1 - block N). The direction vector from the end point of block 1 to the end point of block N-1 is called a gap vector. At this time, a post-compensation intersection vector between (block 1 - gap vector) and a post-compensation intersection vector between (gap vector - block N) is determined, and a path connecting them is created.

In this case, the post-compensation end points of blocks 2 to 6 coincide with the end point of block 1. Thus, after compensation, blocks 2 to 6 will be blocks without tool movement.
If the post-compensation intersection vector of (block 1 - gap vector) and the post-compensation intersection vector of (gap vector - block N) further intersect, vector erasure is first performed in the same way as in "Interference between adjacent three blocks". If the last vectors that remains still intersects, the post-compensation intersection vector of (block 1 - block N) is re-calculated.

In this case, the post-compensation end points of blocks 2 to 7 coincide with the end point of block 1. Thus, after compensation, blocks 2 to 7 will be blocks without tool movement.
If the tool nose radius compensation value is greater than the radius of the specified arc as shown in the figure below, and a command is specified which results in compensation with respect to the inside of the arc, interference is avoided by performing intersection calculation with an arc command being assumed a linear one. In this case, avoided vectors are connected with linear interpolation.
- If no interference avoidance vector exists

If the parallel pocket shown in the figure is to be machined, the end-point vector of block 1 and the end-point vector of block 2 are judged to interfere, and an attempt is made to calculate, as an interference avoidance vector, the intersection vector of the post-compensation path of block 1 and the post-compensation path of block 3. In this case, because blocks 1 and 3 are parallel to each other, no intersection exists. In this case, an alarm will occur immediately before block 1 and the tool will stop.

If the circular pocket shown in the figure is to be machined, the end-point vector of block 1 and the end-point vector of block 2 are judged to interfere, and an attempt is made to calculate, as an interference avoidance vector, the intersection vector of the post-compensation path of block 1 and the post-compensation path of block 3. In this case, because blocks 1 and 3 are circular, no post-compensation intersection exists. In this case, an alarm will occur immediately before block 1 and the tool will stop, as in the previous example.
- If it is judged dangerous to avoid interference

If the acute-angle pocket shown in the figure is to be machined, the end-point vector of block 1 and the end-point vector of block 2 are judged to interfere, and an attempt is made to calculate, as an interference avoidance vector, the intersection vector of the post-compensation path of block 1 and the post-compensation path of block 3. In this case, the movement direction of the post-avoidance path extremely differs from the previously specified direction. If the post-avoidance path extremely differs from that of the original command (90° or greater or 270° or less), interference avoidance operation is judged dangerous; an alarm will occur immediately before block 1 and the tool will stop.

If a pocket in which the bottom is wider than the top, such as that shown in the figure, is to be machined, the end-point vector of block 1 and the end-point vector of block 2 are judged to interfere, and an attempt is made to calculate, as an interference avoidance vector, the intersection vector of the post-compensation path of block 1 and the post-compensation path of block 3. In this case, the relation between blocks 1 and 3 is judged an outer one, the post-avoidance path results in overcutting as compared with the original command. In such a case, interference avoidance operation is judged dangerous; an alarm will occur immediately before block 1 and the tool will stop.
- If further interference with an interference avoidance vector occurs

If the pocket shown in the figure is to be machined, if the number of blocks to read is 3, the end-point vector of block 1 and the end-point vector of block 2 are judged to interfere, and an attempt is made to calculate, as an interference avoidance vector, the intersection vector of the post-compensation path of block 1 and the post-compensation path of block 3. In this case, however, the end-point vector of block 3 that is to be calculated next further interferes with the previous interference avoidance vector. If a further interference occurs to the interference avoidance vector once created and output, the movement in the block will not be performed; an alarm will occur immediately before the block and the tool will stop.

NOTE
1 For "If it is judged dangerous to avoid interference" and "If further interference with an interference avoidance vector occurs", by setting parameter NAA (No. 19607#6) appropriately, it is possible to suppress an alarm to continue machining. For "If no interference avoidance vector exists", however, it is not possible to avoid an alarm regardless of the setting of this parameter.

2 If a single block stop occurs during interference avoidance operation, and an operation is performed which differs from the original movement, such as manual intervention, MDI intervention, tool nose radius compensation value change, intersection calculation is performed with a new path. If such an operation is performed, therefore, an interference may occur again although interference avoidance has been performed once.
5.3.7 Tool Nose Radius Compensation for Input from MDI

Explanation
- MDI operation

During MDI operation, that is, if a program command is specified in MDI mode in the reset state to make a cycle start, intersection calculation is performed for compensation in the same way as in memory operation/DNC operation. Compensation is performed in the same way if a subprogram is called from program memory due to MDI operation.
- MDI intervention

If MDI intervention is performed, that is, if a single block stop is performed to enter the automatic operation stop state in the middle of memory operation, DNC operation, and the like, and a program command is specified in MDI mode to make a cycle start, tool nose radius compensation does not perform intersection calculation, retaining the last compensation vector before the intervention.

\end{align*}
5.4 CORNER CIRCULAR INTERPOLATION (G39)

By specifying G39 in offset mode during tool nose radius compensation, corner circular interpolation can be performed. The radius of the corner circular interpolation equals the compensation value.

Format

In offset mode
G39 ;

or
G39 \{I_J_ I_K_ J_K_\} ;

Explanation

- Corner circular interpolation
  When the command indicated above is specified, corner circular interpolation in which the radius equals compensation value can be performed. G41 or G42 preceding the command determines whether the arc is clockwise or counterclockwise. G39 is a one-shot G code.

- G39 without I, J, or K
  When G39; is programmed, the arc at the corner is formed so that the vector at the end point of the arc is perpendicular to the start point of the next block.

- G39 with I, J, and K
  When G39 is specified with I, J, and K, the arc at the corner is formed so that the vector at the end point of the arc is perpendicular to the vector defined by the I, J, and K values.

Limitation

- Move command
  In a block containing G39, no move command can be specified. Otherwise, an alarm will occur.

- Inner corner
  In an inner corner block, G39 cannot be specified. Otherwise, overcutting will occur.

- Corner arc velocity
  If a corner arc is specified with G39 in G00 mode, the corner arc block velocity will be that of the F command previously specified.
Example
- G39 without I, J, or K

```
N1 Z10.0  ;
N2 G39 ;
N3 X-10.0 ;
```

- G39 with I, J, and K

```
N1 Z10.0  ;
N2 G39 I-1.0 K2.0 ;
N3 X-10.0 Z20.0 ;
```
5.5 AUTOMATIC TOOL OFFSET (G36, G37)

When a tool is moved to the measurement position by execution of a command given to the CNC, the CNC automatically measures the difference between the current coordinate value and the coordinate value of the command measurement position and uses it as the offset value for the tool. When the tool has been already offset, it is moved to the measurement position with that offset value. If the CNC judges that further offset is needed after calculating the difference between the coordinate values of the measurement position and the commanded coordinate values, the current offset value is further offset.

Refer to the instruction manuals of the machine tool builder for details.

NOTE
To use automatic tool offset, set bit 7 (IGA) of parameter No. 6240 to 0.

Explanation

- Coordinate system

When moving the tool to a position for measurement, the coordinate system must be set in advance. (The workpiece coordinate system for programming is used in common.)

- Movement to measurement position

A movement to a measurement position is performed by specifying as follows in the MDI, or MEM mode:

G36 Xxa ; or G37 Zza ;

In this case, the measurement position should be xa or za (absolute programming).

Execution of this command moves the tool at the rapid traverse rate toward the measurement position, lowers the feedrate halfway, then continues to move it until the approach end signal from the measuring instrument is issued.

When the tool tip reaches the measurement position, the measuring instrument outputs the measurement position reach signal to the CNC which stops the tool.

- Offset

The current tool offset value is further offset by the difference between the coordinate value (α or β) when the tool has reached the measurement position and the value of xa or za specified in G36Xxa or G37Zza.

Offset value x = Current offset value x+(α-xa)
Offset value z = Current offset value z+(β-za)

xa : Programmed X-axis measurement point
za : Programmed Z-axis measurement point

These offset values can also be altered from the MDI keyboard.
- Feedrate and alarm

The tool, when moving from the stating position toward the measurement position predicted by \( x_a \) or \( z_a \) in G36 or G37, is feed at the rapid traverse rate across area A. Then the tool stops at point T (\( x_a-\gamma \) or \( z_a-\gamma \)) and moves at the measurement feedrate set by parameter (No. 6241) across areas B, C, and D. If the approach end signal turns on during movement across area B, alarm is generated. If the approach end signal does not turn on before point V, and tool stops at point V and alarm PS0080 is generated.

![Fig. 5.5 (a) Feedrate and alarm](image)

- \( F_R \): Rapid traverse rate
- \( F_P \): Measurement feedrate (set by parameter(No.6241))
- \( \gamma \): Parameters No.6251, No.6252
- \( \epsilon \): Parameters No.6254, No.6255
Example

G50 X760.0 Z1100.0 ; Programming of absolute zero point (Coordinate system setting)
S01 M03 T0101 ; Specifies tool T1, offset number 1, and spindle revolution
G36 X200.0 ; Moves to the measurement position
  If the tool has reached the measurement position at X198.0 ; since the correct measurement position is 200 mm, the offset value is altered by 198.0-200.0=-2.0mm.
G00 X204.0 ; Refracts a little along the X axis.
G37 Z800.0 ; Moves to the Z-axis measurement position.
  If the tool has reached the measurement position at X804.0, the offset value is altered by 804.0-800.0=4.0mm.
T0101 ; Further offsets by the difference.
The new offset value becomes valid when the T code is specified again.
**WARNING**

1. Measurement speed (Fp), γ, and ε are set as parameters (Fp : No.6241, γ : No.6251, ε : No.6254) by machine tool builder. ε must be positive numbers so that γ > ε.
2. Cancel the tool nose radius compensation before G36, G37.
3. A delay or variation in detection of the measurement position arrival signal is 0 to 2 msec on the CNC side excluding the PMC side. Therefore, the measurement error is the sum of 2 msec and a delay or variation (including a delay or variation on the receiver side) in propagation of the measurement position arrival signal on the PMC side, multiplied by the feedrate set in parameter No. 6241.
4. A delay or variation in time after detection of the measurement position arrival signal until a feed stops is 0 to 8 msec. To calculate the amount of overrun, further consider a delay in acceleration/deceleration, servo delay, and delay on the PMC side.
5. When a manual movement is inserted into a movement at a measurement feedrate, return the tool to the position before the inserted manual movement for restart.
6. When tool nose radius compensation is enabled (bit 7 (NCR) of parameter No. 8136 is set to 0), the tool offset amount is calculated with considering the tool nose radius value. Make sure that tool nose radius value is set correctly.

(Condition under which the tool-nose radius compensation is considered)
- For the X-axis (first axis of the basic three axes) : TIP=0/5/7
- For the Z-axis (third axis of the basic three axes) : TIP=0/6/8
- For the Y-axis (second axis of the basic three axes) : TIP=0

![Diagram showing tool offset calculation](attachment:tool_offset.png)

The tool actually moves from point A to point B, but the tool offset value is determined assuming that the tool moves to point C considering the tool nose radius value.

**NOTE**

1. When there is no T code command before G36 or G37, alarm PS0081 is generated.
2. When a T code is specified in the same block as G36 or G37, alarm PS0082 is generated.
By setting the setting-related parameter (bit 1 of parameter No. 0001), a program created in the Series 10/11 program format can be registered in memory for memory operation. Memory operation are possible for the functions which use the same program format as that for the Series 10/11 as well as for the following functions which use a different program format:
- Subprogram calling
- Canned cycle
- Multiple repetitive canned cycle
- Canned cycle for drilling

NOTE
Memory operation are possible only for the functions available in this CNC.

Chapter 6, "MEMORY OPERATION BY Series 10/11 FORMAT", consists of the following sections:

6.1 ADDRESSES AND SPECIFIABLE VALUE RANGE FOR Series 10/11 PROGRAM FORMAT..................249
6.2 SUBPROGRAM CALLING..................................................249
6.3 CANNED CYCLE.......................................................250
6.4 MULTIPLE REPETITIVE CANNED CYCLE...............272
6.5 CANNED CYCLE FOR DRILLING .........................315
6.1 ADDRESSES AND SPECIFIABLE VALUE RANGE FOR Series 10/11 PROGRAM FORMAT

Some addresses which cannot be used for this CNC can be used in the Series 10/11 program format. The specifiable value range for the Series 10/11 program format is basically the same as that for this CNC. Sections II-6.2 to II-6.5 describe the addresses with a different specifiable value range. If a value out of the specifiable value range is specified, an alarm is issued.

6.2 SUBPROGRAM CALLING

Format

```
M98 Pxxxx Lyyyy ;
```

- Address

Address L cannot be used in this CNC tape format but can be used in the Series 10/11 format.

- Subprogram number

The specifiable value range is the same as that for this CNC (1 to 9999). If a value of more than four digits is specified, the last four digits are assumed as the subprogram number.

- Repetition count

The repetition count L can be specified in the range from 1 to 9999. If no repetition count is specified, 1 is assumed.
6.3 CANNED CYCLE

Explanation

There are three canned cycles: the outer diameter/internal diameter cutting canned cycle (G90), the threading canned cycle (G92), and the end face turning canned cycle (G94).

NOTE

1. Explanatory figures in this section use the ZX plane as the selected plane, diameter programming for the X-axis, and radius programming for the Z-axis. When radius programming is used for the X-axis, change U/2 to U and X/2 to X.
2. A canned cycle can be performed on any plane (including parallel axes for plane definition). When G code system A is used, however, U, V, and W cannot be set as a parallel axis.
3. The direction of the length means the direction of the first axis on the plane as follows:
   - ZX plane: Z-axis direction
   - YZ plane: Y-axis direction
   - XY plane: X-axis direction
4. The direction of the end face means the direction of the second axis on the plane as follows:
   - ZX plane: X-axis direction
   - YZ plane: Z-axis direction
   - XY plane: Y-axis direction
6.3.1 Outer Diameter/Internal Diameter Cutting Cycle (G90)

This cycle performs straight or taper cutting in the direction of the length.

6.3.1.1 Straight cutting cycle

**Format**

\[
\text{G90X(U)Z(W)F_;}
\]

\[X_,Z_ : \text{Coordinates of the cutting end point (point A' in the figure below) in the direction of the length}\]

\[U_,W_ : \text{Travel distance to the cutting end point (point A' in the figure below) in the direction of the length}\]

\[F_ : \text{Cutting feedrate}\]

A straight cutting cycle performs four operations:

1. Operation 1 moves the tool from the start point (A) to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

2. Operation 2 moves the tool to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in cutting feed. (The tool is moved to the cutting end point (A') in the direction of the length.)

3. Operation 3 moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in cutting feed.

4. Operation 4 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)
6. MEMORY OPERATION
USING Series 10/11 FORMAT

NOTE
In single block mode, operations 1, 2, 3 and 4 are performed by pressing the cycle start button once.

- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
6.3.1.2 Taper cutting cycle

Format

<table>
<thead>
<tr>
<th>Plane</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZpXp-plane</td>
<td>G90 X(U) Z(W) I F ;</td>
</tr>
<tr>
<td>YpZp-plane</td>
<td>G90 Y(V) Z(W) K F ;</td>
</tr>
<tr>
<td>XpYp-plane</td>
<td>G90 X(U) Y(V) J F ;</td>
</tr>
</tbody>
</table>

X_,Y_,Z_ : Coordinates of the cutting end point (point A' in the figure below) in the direction of the length

U_,V_,W_ : Travel distance to the cutting end point (point A' in the figure below) in the direction of the length

I_,J_,K_ : Taper amount (I in the figure below)

F_ : Cutting feedrate

**Explanation**

Address I, J, or K for specifying a taper varies with the plane selected. The figure of a taper is determined by the coordinates of the cutting end point (A') in the direction of the length and the sign of the taper amount (address I, J, or K). For the cycle in the figure above, a minus sign is added to the taper amount.

**NOTE**

The increment system of address I, J, or K for specifying a taper depends on the increment system for the reference axis. Specify a radius value at I, J, or K.
- Operations

A taper cutting cycle performs the same four operations as a straight cutting cycle. However, operation 1 moves the tool from the start point (A) to the position obtained by adding the taper amount to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

Operations 2, 3, and 4 after operation 1 are the same as for a straight cutting cycle.

**NOTE**

In single block mode, operations 1, 2, 3, and 4 are performed by pressing the cycle start button once.

- Relationship between the sign of the taper amount and tool path

The tool path is determined according to the relationship between the sign of the taper amount (address I, J, or K) and the cutting end point in the direction of the length in the absolute or incremental programming as follows.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. U &lt; 0, W &lt; 0, I &lt; 0</td>
<td>2. U &gt; 0, W &lt; 0, I &gt; 0</td>
</tr>
</tbody>
</table>

- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
6.3.2 Threading Cycle (G92)

6.3.2.1 Straight threading cycle

**Format**

G92 X(U) Z(W) F Q;

- X, Z: Coordinates of the cutting end point (point A' in the figure below) in the direction of the length
- U, W: Travel distance to the cutting end point (point A' in the figure below) in the direction of the length
- Q: Angle for shifting the threading start angle
  - (Increment: 0.001 degrees, Valid setting range: 0 to 360 degrees)
- F: Thread lead (L in the figure below)

![Diagram of threading cycle](image)

**Explanation**

The ranges of thread leads and restrictions related to the spindle speed are the same as for threading with G32.

**- Operations**

A straight threading cycle performs four operations:

1. **Operation 1** moves the tool from the start point (A) to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.
2. **Operation 2** moves the tool to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in cutting feed. At this time, thread chamfering is performed.
3. **Operation 3** moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in rapid traverse. (Retraction after chamfering)
6. MEMORY OPERATION
USING Series 10/11 FORMAT

(4) Operation 4 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)

⚠️ CAUTION
Notes on this threading are the same as in threading in G32. However, a stop by feed hold is as follows: Stop after completion of path 3 of threading cycle.

NOTE
In the single block mode, operations 1, 2, 3, and 4 are performed by pressing cycle start button once.

- Canceling the mode
To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.

- Acceleration/deceleration for threading after interpolation
Acceleration/deceleration for threading after interpolation is acceleration/deceleration of exponential interpolation type. By setting bit 5 (THLx) of parameter No. 1610, the same acceleration/deceleration as for cutting feed can be selected. (The settings of bit 0 (CTLx) of parameter No. 1610 are followed.) However, as a time constant and FL feedrate, the settings of parameter No. 1626 and No. 1627 for the threading cycle are used.

- Time constant and FL feedrate for threading
The time constant for acceleration/deceleration after interpolation for threading specified in parameter No. 1626 and the FL feedrate specified in parameter No. 1627 are used.

- Thread chamfering
Thread chamfering can be performed. A signal from the machine tool, initiates thread chamfering. The chamfering distance r is specified in a range from 0.1L to 12.7L in 0.1L increments by parameter No. 5130. (In the above expression, L is the thread lead.) A thread chamfering angle between 1 to 89 degrees can be specified in parameter No. 5131. When a value of 0 is specified in the parameter, an angle of 45 degrees is assumed.
For thread chamfering, the same type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate as for threading are used.

NOTE
Common parameters for specifying the amount and angle of thread chamfering are used for this cycle and threading cycle with G76.
- Retraction after chamfering

The following table lists the feedrate, type of acceleration/deceleration after interpolation, and time constant of retraction after chamfering.

<table>
<thead>
<tr>
<th>Parameter CFR (No. 1611#0)</th>
<th>Parameter No. 1466</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Other than 0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and retraction feedrate specified in parameter No. 1466.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and rapid traverse rate specified in parameter No. 1420.</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).</td>
</tr>
</tbody>
</table>

By setting bit 4 (ROC) of parameter No. 1403 to 1, rapid traverse override can be disabled for the feedrate of retraction after chamfering.

NOTE
During retraction, the machine does not stop with an override of 0% for the cutting feedrate regardless of the setting of bit 4 (RF0) of parameter No. 1401.

- Shifting the start angle

Address Q can be used to shift the threading start angle. The start angle (Q) increment is 0.001 degrees and the valid setting range is between 0 and 360 degrees. No decimal point can be specified.
Feed hold in a threading cycle (threading cycle retract)

Feed hold may be applied during threading (operation 2). In this case, the tool immediately retracts with chamfering and returns to the start point on the second axis (X-axis), then the first axis (Z-axis) on the plane.

The chamfered angle is the same as that at the end point.

**CAUTION**

Another feed hold cannot be made during retreat.

- Inch threading

Inch threading specified with address E is allowed.
6.3.2.2 **Taper threading cycle**

**Format**

\[
\begin{align*}
&\text{ZpXp-plane} \\
&\quad \text{G92 X(U)} \_ Z(W) \_ I \_ F \_ Q \_ ; \\
&\text{YpZp-plane} \\

\end{align*}
\]

- **X_\_,Y_\_,Z_\_**: Coordinates of the cutting end point (point A’ in the figure below) in the direction of the length
- **U_\_,V_\_,W_\_**: Travel distance to the cutting end point (point A’ in the figure below) in the direction of the length
- **Q_\_**: Angle for shifting the threading start angle (Increment: 0.001 degrees, Valid setting range: 0 to 360 degrees)
- **I_\_,J_\_,K_\_**: Taper amount (I in the figure below)
- **F_\_**: Thread lead (L in the figure below)

---

*Fig. 6.3.2 (d) Taper threading cycle*
6. MEMORY OPERATION

USING Series 10/11 FORMAT

PROGRAMMING

6. MEMORY OPERATION

USING Series 10/11 FORMAT

Explanation

The ranges of thread leads and restrictions related to the spindle speed are the same as for threading with G32.

The figure of a taper is determined by the coordinates of the cutting end point (A') in the direction of the length and the sign of the taper amount (address I, J, or K). For the cycle in the figure above, a minus sign is added to the taper amount.

**NOTE**

The increment system of address I, J, or K for specifying a taper depends on the increment system for the reference axis. Specify a radius value at I, J, or K.

**- Operations**

A taper threading cycle performs the same four operations as a straight threading cycle.

However, operation 1 moves the tool from the start point (A) to the position obtained by adding the taper amount to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in rapid traverse.

Operations 2, 3, and 4 after operation 1 are the same as for a straight threading cycle.

⚠️ **CAUTION**

Notes on this threading are the same as in threading in G32. However, a stop by feed hold is as follows; Stop after completion of path 3 of threading cycle.

**NOTE**

In the single block mode, operations 1, 2, 3, and 4 are performed by pressing cycle start button once.
- Relationship between the sign of the taper amount and tool path

The tool path is determined according to the relationship between the sign of the taper amount (address I, J, or K) and the cutting end point in the direction of the length in the absolute or incremental programming as follows.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>

See the pages on which a straight threading cycle is explained.
6.3.3 End Face Turning Cycle (G94)

6.3.3.1 Face cutting cycle

Format

G94 X(U)_Z(W)_F_;  
X_,Z_ : Coordinates of the cutting end point (point A’ in the figure below) in the direction of the end face  
U_,W_ : Travel distance to the cutting end point (point A’ in the figure below) in the direction of the end face  
F_ : Cutting feedrate

- Operations

A face cutting cycle performs four operations:

1. Operation 1 moves the tool from the start point (A) to the specified coordinate of the first axis on the plane (specified Z-coordinate for the ZX plane) in rapid traverse.

2. Operation 2 moves the tool to the specified coordinate of the second axis on the plane (specified X-coordinate for the ZX plane) in cutting feed. (The tool is moved to the cutting end point (A’) in the direction of the end face.)

3. Operation 3 moves the tool to the start coordinate of the first axis on the plane (start Z-coordinate for the ZX plane) in cutting feed.

4. Operation 4 moves the tool to the start coordinate of the second axis on the plane (start X-coordinate for the ZX plane) in rapid traverse. (The tool returns to the start point (A).)

NOTE

In single block mode, operations 1, 2, 3, and 4 are performed by pressing the cycle start button once.
- Canceling the mode

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
6.3.3.2 Taper cutting cycle

Format

ZpXp-plane

To cancel the canned cycle mode, specify a group 01 G code other than G90, G92, or G94.
6. MEMORY OPERATION
USING Series 10/11 FORMAT
PROGRAMMING

6.3.4 How to Use Canned Cycles

An appropriate canned cycle is selected according to the shape of the material and the shape of the product.

- Straight cutting cycle (G90)

- Taper cutting cycle (G90)
- Face cutting cycle (G94)

- Face taper cutting cycle (G94)
6.3.5 Canned Cycle and Tool Nose Radius Compensation

When tool nose radius compensation is applied, the tool nose center path and offset direction are as shown below. At the start point of a cycle, the offset vector is canceled. Offset start-up is performed for the movement from the start point of the cycle. The offset vector is temporarily canceled again at the return to the cycle start point and offset is applied again according to the next move command. The offset direction is determined depending of the cutting pattern regardless of the G41 or G42 mode.

Threading cycle (G92)

Tool nose radius compensation cannot be applied.
Differences between this CNC and the Series 0\textit{i}-C

**NOTE**

This CNC is the same as the Series 0\textit{i}-C in the offset direction, but differs from the series in the tool nose radius center path.

- **For this CNC**
  Cycle operations of a canned cycle are replaced with G00 or G01. In the first block to move the tool from the start point, start-up is performed. In the last block to return the tool to the start point, offset is canceled.

- **For the Series 0\textit{i}-C**
  This series differs from this CNC in operations in the block to move the tool from the start point and the last block to return it to the start point. For details, refer to "Series 0\textit{i}-C Operator's Manual."

How compensation is applied for the Series 0\textit{i}-C

**G90**

- Tool nose radius center path
- Whole tool nose
- Programmed path

**G94**

- Tool nose radius center path
- Whole tool nose

6. MEMORY OPERATION
USING Series 10/11 FORMAT
PROGRAMMING

6.3.6 Restrictions on Canned Cycles

Limitation
- Modal

Since data items X (U), Z (W), and R in a canned cycle are modal values common to G90, G92, and G94. For this reason, if a new X (U), Z (W), or R value is not specified, the previously specified value is effective.

Thus, when the travel distance along the Z-axis does not vary as shown in the program example below, a canned cycle can be repeated only by specifying the travel distance along the X-axis.

Example

```
Workpiece

66 X axis
0

The cycle in the above figure is executed by the following program:
N030 G90 U-8.0 W-66.0 F0.4;
N031 U-16.0;
N032 U-24.0;
N033 U-32.0;
```

The modal values common to canned cycles are cleared when a one-shot G code other than G04 is specified.

Since the canned cycle mode is not canceled by specifying a one-shot G code, a canned cycle can be performed again by specifying modal values. If no modal values are specified, no cycle operations are performed.

When G04 is specified, G04 is executed and no canned cycle is performed.
- Block in which no move command is specified

In a block in which no move command is specified in the canned cycle mode, a canned cycle is also performed. For example, a block containing only EOB or a block in which none of the M, S, and T codes, and move commands are specified is of this type of block. When an M, S, or T code is specified in the canned cycle mode, the corresponding M, S, or T function is executed together with the canned cycle. If this is inconvenient, specify a group 01 G code (G00 or G01) other than G90, G92, or G94 to cancel the canned cycle mode, and specify an M, S, or T code, as in the program example below. After the corresponding M, S, or T function has been executed, specify the canned cycle again.

Example

N003 T0101;
:
:
N010 G90 X20.0 Z10.0 F0.2;
N011 G00 T0202; ← Cancels the canned cycle mode.
N012 G90 X20.5 Z10.0;

- Plane selection command

Specify a plane selection command (G17, G18, or G19) before setting a canned cycle or specify it in the block in which the first canned cycle is specified.

If a plane selection command is specified in the canned cycle mode, the command is executed, but the modal values common to canned cycles are cleared.

If an axis which is not on the selected plane is specified, alarm PS0330 is issued.

- Parallel axis

When G code system A is used, U, V, and W cannot be specified as a parallel axis.

- Reset

If a reset operation is performed during execution of a canned cycle when any of the following states for holding a modal G code of group 01 is set, the modal G code of group 01 is replaced with the G01 mode:

- Reset state (bit 6 (CLR) of parameter No. 3402 = 0)
- Cleared state (bit 6 (CLR) of parameter No. 3402 = 1) and state where the modal G code of group 01 is held at reset time (bit 1 (C01) of parameter No. 3406 = 1)

Example of operation

If a reset is made during execution of a canned cycle (X0 block) and the X20.Z1. command is executed, linear interpolation (G01) is performed instead of the canned cycle.
6. MEMORY OPERATION
USING Series 10/11 FORMAT PROGRAMMING

6.4 MULTIPLE REPETITIVE CANNED CYCLE

The multiple repetitive canned cycle is canned cycles to make CNC programming easy. For instance, the data of the finish workpiece shape describes the tool path for rough machining. And also, a canned cycles for the threading is available.

NOTE

1. Explanatory figures in this section use the ZX plane as the selected plane, diameter programming for the X-axis, and radius programming for the Z-axis. When radius programming is used for the X-axis, change U/2 to U and X/2 to X.

2. A multiple repetitive canned cycle can be performed on any plane (including parallel axes for plane definition). When G code system A is used, however, U, V, and W cannot be set as a parallel axis.
6.4.1 Stock Removal in Turning (G71)

There are two types of stock removal in turning: Type I and II.

**Format**

USING Series 10/11 FORMAT

Target figure

Fig. 6.4.1 (b) Cutting path of an outer surface rough cutting cycle with rough cutting finishing allowance (type I)
6. MEMORY OPERATION
USING Series 10/11 FORMAT
PROGRAMMING

Explanation
- Operations

If a target figure passing through A, A’, and B in this order is given by the program, a workpiece is cut away by depth of cut \( \Delta d \) at a time. The machining path varies as follows depending on whether the rough machining finishing allowance is specified.

(1) When the rough cutting finishing allowance is not specified
Cutting is performed by depth of cut \( \Delta d \) with finishing allowances \( \Delta u/2 \) and \( \Delta w \) left, and rough cutting as finishing is performed according to the target figure program after the last machining.

(2) When the rough cutting finishing allowance is specified
Cutting is performed by depth of cut \( \Delta d \) with cutting allowances \( \Delta u/2+\Delta i \) and \( \Delta w+\Delta k \) left, and the tool returns to the start point (A) after the last cutting is performed. Then, rough machining as finishing is performed along the target figure to remove cutting allowances \( \Delta i \) and \( \Delta k \).

Upon completion of rough machining as finishing, the block next to the sequence block specified by Q is executed.

**NOTE**

1. F, S, and T functions which are specified in the move command between points A and B are ineffective and those specified in G71 block or the previous block are effective. M and second auxiliary functions are treated in the same way as F, S, and T functions.

2. When the constant surface speed control function is enabled (bit 0 (SSC) of parameter No. 8133 is set to 1), the G96 or G97 command specified in the move command between points A and B is ignored. If you want to enable the G96 or G97 command, specify the command in the G71 or previous block.

- Escaping amount (e)

The escaping amount (e) is set in parameter No. 5133.

<table>

</tr>
</thead>
<tbody>
<tr>
<td>5133</td>
<td>Depends on the increment system for the reference axis.</td>
<td>Radius programming</td>
<td>Not required</td>
</tr>
</tbody>
</table>
- Target figure
Patterns

The following four cutting patterns are considered. All of these cutting cycles cut the workpiece with moving the tool in parallel to the first axis on the plane (Z-axis for the ZX plane). At this time, the signs of the finishing allowances of ∆u and ∆w are as follows:

![Four target figure patterns](image)

Fig. 6.4.1 (c) Four target figure patterns

Limitation

(1) For U(+), a figure for which a position higher than the cycle start point is specified cannot be machined. For U(-), a figure for which a position lower than the cycle start point is specified cannot be machined.

(2) For type I, the figure must show monotone increase or decrease along the first and second axes on the plane.

(3) For type II, the figure must show monotone increase or decrease along the first axis on the plane.

Start block

In the start block in the program for a target figure (block with sequence number ns in which the path between A and A' is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.

When G00 is specified, positioning is performed along A-A'. When G01 is specified, linear interpolation is performed with cutting feed along A-A'.

In this start block, also select type I or II.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

- 278 -

Check functions

During cycle operation, whether the target figure shows monotone increase or decrease is always checked.

**NOTE**
When tool nose radius compensation is applied, the target figure to which compensation is applied is checked.

The following checks can also be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
<tr>
<td>Checks the target figure before cycle operation. (Also checks that a block with the sequence number specified at address Q is contained.)</td>
<td>Enabled when bit 2 (FCK) of parameter No. 5104 is set to 1.</td>
</tr>
</tbody>
</table>

- Types I and II

**Selection of type I or II**

For G71, there are types I and II. When the target figure has pockets, be sure to use type II. Escaping operation after rough cutting in the direction of the first axis on the plane (Z-axis for the ZX plane) differs between types I and II. With type I, the tool escapes to the direction of 45 degrees. With type II, the tool cuts the workpiece along the target figure. When the target figure has no pockets, determine the desired escaping operation and select type I or II.

**Selecting type I or II**

In the start block for the target figure (sequence number ns), select type I or II.

1. When type I is selected
   Specify the second axis on the plane (X-axis for the ZX plane).
   Do not specify the first axis on the plane (Z-axis for the ZX plane).

2. When type II is selected
   Specify the second axis on the plane (X-axis for the ZX plane) and first axis on the plane (Z-axis for the ZX plane).
   When you want to use type II without moving the tool along the first axis on the plane (Z-axis for the ZX plane), specify the incremental programming with travel distance 0 (W0 for the ZX plane).
- Type I

(1) In the block with sequence number ns, only the second axis on the plane (X-axis (U-axis) for the ZX plane) must be specified.

**Example**

ZX plane
G71 V10.0 R5.0 ;
G71 P100 Q200....;
N100 X(U)_ ;  (Specifies only the second axis on the plane.)
N200.........;

(2) The figure along path A'-B must show monotone increase or decrease in the directions of both axes forming the plane (Z- and X-axes for the ZX plane). It must not have any pocket as shown in the figure below.

![Diagram of a figure which does not show monotone increase or decrease (type I)](image)

**Fig. 6.4.1 (d)  Figure which does not show monotone increase or decrease (type I)**

⚠️ **CAUTION**

If a figure does not show monotone change along the first or second axis on the plane, alarm PS0064 or 0329 is issued. If the movement does not show monotone change, but is very small, and it can be determined that the movement is not dangerous, however, the permissible amount can be specified in parameters Nos. 5145 and 5146 to specify that the alarm is not issued in this case.
(3) The tool escapes to the direction of 45 degrees in cutting feed after rough cutting.

![Fig. 6.4.1 (e) Cutting in the direction of 45 degrees (type I)](image)

(4) Immediately after the last cutting, rough cutting is performed as finishing along the target figure. Bit 1 (RF1) of parameter No. 5105 can be set to 1 so that rough cutting as finishing is not performed. When the rough cutting finishing allowance is specified, however, rough cutting as finishing is performed.

- Type II

![Fig. 6.4.1 (f) Cutting path in stock removal in turning (type II)](image)

When the figure program for instructing a target figure passing through A, A', and B in this order is specified, a workpiece is cut away by depth of cut \( \Delta d \) at a time. In type II, cutting is performed along the figure after rough cutting in the direction of the plane first axis (z-axis for the ZX plane).

The machining path varies as follows depending on whether the rough machining finishing allowance is specified.
(1) When the rough cutting finishing allowance is not specified
Cutting is performed by depth of cut $\Delta d$ with finishing allowances $\Delta u/2$ and $\Delta w$ left, and the tool returns to the start point (A) after the last cutting is performed (one pocket is assumed because $P_n \rightarrow P_m$ is parallel to the $z$-axis in the above figure, and the zone is cut). Then, rough machining as finishing is performed according to the finishing figure program with finishing allowances $\Delta u/2$ and $\Delta w$ left.

(2) When the rough cutting finishing allowance is specified
Cutting is performed by depth of cut $\Delta d$ with cutting allowances $\Delta u/2+\Delta i$ and $\Delta w+\Delta k$ left, and the tool returns to the start point (A) after the last cutting is performed. Then, rough machining as finishing is performed along the target figure to remove cutting allowances $\Delta i$ and $\Delta k$.

Upon completion of rough machining as finishing, the block next to the sequence block specified by Q is executed.

Type II differs from type I in the following points:
(1) In the block with sequence number ns, the two axes forming the plane (X-axis (U-axis) and Z-axis (W-axis) for the ZX plane) must be specified. When you want to use type II without moving the tool along the Z-axis on the ZX plane in the first block, specify W0.

Example

ZX plane
G71 V10.0 R5.0;
G71 P100 Q200.......;
N100 X(U) Z(W) ;
 : ;
 : ;
N200..............;

(2) The figure need not show monotone increase or decrease in the direction of the second axis on the plane (X-axis for the ZX plane) and it may have concaves (pockets).

![Figure 6.4.1 (g) Figure having pockets (type II)](image)

The figure must show monotone change in the direction of the first axis on the plane (Z-axis for the ZX plane), however. The following figure cannot be machined.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

---

**CAUTION**

For a figure along which the tool moves backward along the first axis on the plane during cutting operation (including a vertex in an arc command), the cutting tool may contact the workpiece. For this reason, for a figure which does not show monotone change, alarm PS0064 or PS0329 is issued. If the movement does not show monotone change, but is very small, and it can be determined that the movement is not dangerous, however, the permissible amount can be specified in parameter No. 5145 to specify that the alarm is not issued in this case.

The first cut portion need not be vertical. Any figure is permitted if monotone change is shown in the direction of the first axis on the plane (Z-axis for the ZX plane).

---

Fig. 6.4.1 (i)  Figure which can be machined (type II)
(3) After turning, the tool cuts the workpiece along its figure and escapes in cutting feed.

The escaping amount $e$ after cutting is set in parameter No. 5133. When moving from the bottom, however, the tool escapes to the direction of 45 degrees.

(4) When a position parallel to the first axis on the plane (Z-axis for the ZX plane) is specified in a block in the program for the target figure, it is assumed to be at the bottom of a pocket.

(5) After all rough cutting terminates along the first axis on the plane (Z-axis for the ZX plane), the tool temporarily returns to the cycle start point. At this time, when there is a position whose height equals to that at the start point, the tool passes through the point in the position obtained by adding depth of cut $\Delta d$ to the position of the figure and returns to the start point. Then, rough cutting is performed as finishing along the target figure. At this time, the tool passes through the point in the obtained position (to which depth of cut $\Delta d$ is added) when returning to the start point.

Bit 2 (RF2) of parameter No. 5105 can be set to 1 so that rough cutting as finishing is not performed.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

6. MEMORY OPERATION
USING Series 10/11 FORMAT

(6) Order and path for rough cutting of pockets
Rough cutting is performed in the following order.
(a) When the figure shows monotone decrease along the first
axis on the plane (Z-axis for the ZX plane)

(b) When the figure shows monotone increase along the first
axis on the plane (Z-axis for the ZX plane)
The path in rough cutting is as shown below.

![Fig. 6.4.1 (o) Cutting path for multiple pockets (type II)](image)

The following figure shows how the tool moves after rough cutting for a pocket in detail.

![Fig. 6.4.1 (p) Details of motion after cutting for a pocket (type II)](image)

Cuts the workpiece at the cutting feedrate and escapes to the direction of 45 degrees. (Operation 19)
Then, moves to the height of point D in rapid traverse. (Operation 20)
Then, moves to the position the amount of g before point D. (Operation 21)
Finally, moves to point D in cutting feed.
The clearance g to the cutting feed start position is set in parameter No. 5134.
For the last pocket, after cutting the bottom, the tool escapes to the direction of 45 degrees and returns to the start point in rapid traverse. (Operations 34 and 35)
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

CAUTION
1 This CNC differs from the Series 0i-C in cutting of a pocket.
The tool first cuts the nearest pocket to the start point. After cutting of the pocket terminates, the tool moves to the nearest but one pocket and starts cutting.
2 When the figure has a pocket, generally specify a value of 0 for $\Delta w$ (finishing allowance). Otherwise, the tool may dig into the wall on one side.

- Tool nose radius compensation

When using tool nose radius compensation, specify a tool nose radius compensation command (G41, G42) before a multiple repetitive canned cycle command (G70, G71, G72, G73) and specify the cancel command (G40) outside the blocks (from the block specified with P to the block specified with Q) specifying a target finishing figure. If a tool nose radius compensation command (G40, G41, or G42) is specified in the G70, G71, G72, or G73 command, alarm PS0325 is issued.

When this cycle is specified in the tool nose radius compensation mode, offset is temporarily canceled during movement to the start point. Start-up is performed in the first block. Offset is temporarily canceled again at the return to the cycle start point after termination of cycle operation. Start-up is performed again according to the next move command. This operation is shown in the figure below.

This cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.
Fig. 6.4.1 (q) Path when tool nose radius compensation is applied

- Movement to the previous turning start point

Movement to the turning start point is performed with two operations. (Operations 1 and 2 in the figure below.) As movement to the present turning start point, operation 1 temporarily moves the tool to the previous turning start point, then operation 2 moves the tool to the present turning start point.

Operation 1 moves the tool in cutting feed. Operation 2 moves the tool according to the mode (G00 or G01) specified in the start block in the geometry program.

Bit 0 (ASU) of parameter No. 5107 can be set to 1 so that operation 1 moves the tool in rapid traverse.

NOTE
To perform pocketing in the tool nose radius compensation mode, specify the linear block A-A' outside the workpiece and specify the figure of an actual pocket. This prevents a pocket from being dug.

- Target figure Patterns

The following four cutting patterns are considered. All of these cutting cycles cut the workpiece with moving the tool in parallel to the second axis on the plane (X-axis for the ZX plane). At this time, the signs of the finishing allowances of $\Delta u$ and $\Delta w$ are as follows:

Fig. 6.4.2 (s)  Signs of the values specified at U and W in stock removal in facing
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

Limitation

(1) For W(+), a figure for which a position higher than the cycle start point is specified cannot be machined. For W(-), a figure for which a position lower than the cycle start point is specified cannot be machined.

(2) For type I, the figure must show monotone increase or decrease along the first and second axes on the plane.

(3) For type II, the figure must show monotone increase or decrease along the second axis on the plane.

Start block

In the start block in the program for a target figure (block with sequence number ns in which the path between A and A' is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.

When G00 is specified, positioning is performed along A-A'. When G01 is specified, linear interpolation is performed with cutting feed along A-A'.

In this start block, also select type I or II.

Check functions

During cycle operation, whether the target figure shows monotone increase or decrease is always checked.

**NOTE**

When tool nose radius compensation is applied, the target figure to which compensation is applied is checked.

The following checks can also be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
<tr>
<td>Checks the target figure before cycle operation.</td>
<td>Enabled when bit 2 (FCK) of parameter No. 5104 is set to 1.</td>
</tr>
<tr>
<td>(Also checks that a block with the sequence number specified at address Q is contained.)</td>
<td></td>
</tr>
</tbody>
</table>

- Types I and II
Selection of type I or II

For G72, there are types I and II.

When the target figure has pockets, be sure to use type II.

Escaping operation after rough cutting in the direction of the second axis on the plane (X-axis for the ZX plane) differs between types I and II. With type I, the tool escapes to the direction of 45 degrees. With type II, the tool cuts the workpiece along the target figure.

When the target figure has no pockets, determine the desired escaping operation and select type I or II.
Selecting type I or II

In the start block for the target figure (sequence number ns), select type I or II.

1. When type I is selected
   Specify the first axis on the plane (Z-axis for the ZX plane). Do not specify the second axis on the plane (X-axis for the ZX plane).

2. When type II is selected
   Specify the second axis on the plane (X-axis for the ZX plane) and first axis on the plane (Z-axis for the ZX plane).
   When you want to use type II without moving the tool along the second axis on the plane (X-axis for the ZX plane), specify the incremental programming with travel distance 0 (U0 for the ZX plane).

- Type I

G72 differs from G71 in the following points:

1. G72 cuts the workpiece with moving the tool in parallel with the second axis on the plane (X-axis on the ZX plane).

2. In the start block in the program for a target figure (block with sequence number ns), only the first axis on the plane (Z-axis (W-axis) for the ZX plane) must be specified.

- Type II

G72 differs from G71 in the following points:

1. G72 cuts the workpiece with moving the tool in parallel with the second axis on the plane (X-axis on the ZX plane).

2. The figure need not show monotone increase or decrease in the direction of the first axis on the plane (Z-axis for the ZX plane) and it may have concaves (pockets). The figure must show monotone change in the direction of the second axis on the plane (X-axis for the ZX plane), however.

3. When a position parallel to the second axis on the plane (X-axis for the ZX plane) is specified in a block in the program for the target figure, it is assumed to be at the bottom of a pocket.

4. After all rough cutting terminates along the second axis on the plane (X-axis for the ZX plane), the tool temporarily returns to the start point. Then, rough cutting as finishing is performed.

- Tool nose radius compensation

See the pages on which G71 is explained.

- Movement to the previous turning start point

See the pages on which G71 is explained.
6. MEMORY OPERATION
USING Series 10/11 FORMAT
PROGRAMMING

6.4.3 Pattern Repeating (G73)

This function permits cutting a fixed pattern repeatedly, with a pattern being displaced bit by bit. By this cutting cycle, it is possible to efficiently cut workpiece whose rough shape has already been made by a rough machining, forging or casting method, etc.

Format

- Δi : Distance of escape in the direction of the second axis on the plane (X-axis for the ZX plane)
- Δk : Distance of escape in the direction of the first axis on the plane (Z-axis for the ZX plane)
- d : The number of division
  - This value is the same as the repetitive count for rough cutting.
- ns : Sequence number of the first block for the program of finishing shape.
- nf : Sequence number of the last block for the program of finishing shape.
- Δu : Distance of the finishing allowance in the direction of the second axis on the plane (X-axis for the ZX plane)
- Δw : Distance of the finishing allowance in the direction of the first axis on the plane (Z-axis for the ZX plane)
- f, s, t : Any F, S, and T function contained in the blocks between sequence number "ns" and "nf" are ignored, and the F, S, and T functions in this G73 block are effective.

NOTE
- Even if pocket calculator type decimal point programming is specified (bit 0 (DPI) of parameter No. 3401 = 1), the unit of address D is the least input increment. In addition, when a decimal point is input in address D, alarm PS0007 is issued.
### 6.MEMORY OPERATION USING Series 10/11 FORMAT

#### 6. MEMORY OPERATION

<table>
<thead>

<td>Required</td>
</tr>
<tr>
<td>( \Delta w )</td>
<td>Depends on the increment system for the reference axis.</td>
<td>Depends on diameter/radius programming for the first axis on the plane.</td>
<td>Required</td>
</tr>
</tbody>
</table>

#### Explanation

- **Operations**

When a target figure passing through A, A', and B in this order is given by a program, rough cutting is performed the specified number of times, with the finishing allowance specified by \( \Delta u/2 \) and \( \Delta w \) left.

#### NOTE

1. After cycle operation terminates, the tool returns to point A.
2. F, S, and T functions which are specified in the move command between points A and B are ineffective and those specified in G73 block or the previous block are effective. M and second auxiliary functions are treated in the same way as F, S, and T functions.
- Target figure patterns

As in the case of G71, there are four target figure patterns. Be careful about signs of $\Delta u$, $\Delta w$, $\Delta i$, and $\Delta k$ when programming this cycle.

- Start block

In the start block in the program for the target figure (block with sequence number ns in which the path between A and A' is specified), G00 or G01 must be specified. If it is not specified, alarm PS0065 is issued.

When G00 is specified, positioning is performed along A-A'. When G01 is specified, linear interpolation is performed with cutting feed along A-A'.

- Check function

The following check can be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
</tbody>
</table>

- Tool nose radius compensation

Like G71, this cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.
6.4.4 Finishing Cycle (G70)

After rough cutting by G71, G72 or G73, the following command permits finishing.

**Format**

```
G70 P(ns) Q(nf) ;
```

- **ns**: Sequence number of the first block for the program of finishing shape.
- **nf**: Sequence number of the last block for the program of finishing shape.

**Explanation**

- **Operations**
  
The blocks with sequence numbers ns to nf in the program for a target figure are executed for finishing. The F, S, T, M, and second auxiliary functions specified in the G71, G72, or G73 block are ignored and the F, S, T, M, and second auxiliary functions specified in the blocks with sequence numbers ns to nf are effective. When cycle operation terminates, the tool is returned to the start point in rapid traverse and the next G70 cycle block is read.

- **Target figure check function**
  
The following check can be made.

<table>
<thead>
<tr>
<th>Check</th>
<th>Related parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Checks that a block with the sequence number specified at address Q is contained in the program before cycle operation.</td>
<td>Enabled when bit 2 (QSR) of parameter No. 5102 is set to 1.</td>
</tr>
</tbody>
</table>

- **Storing P and Q blocks**
  
When rough cutting is executed by G71, G72, or G73, up to three memory addresses of P and Q blocks are stored. By this, the blocks indicated by P and Q are immediately found at execution of G70 without searching memory from the beginning for them. After some G71, G72, and G73 rough cutting cycles are executed, finishing cycles can be performed by G70 at a time. At this time, for the fourth and subsequent rough cutting cycles, the cycle time is longer because memory is searched for P and Q blocks.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

**Example**

G71 P100 Q200 ...;
N100 ...;
...;
...
N200 ...;
G71 P300 Q400 ...;
N300 ...;
...;
...
N400 ...;
...;
...
G70 P100 Q200 ; (Executed without a search for the first to third cycles)
G70 P300 Q400 ; (Executed after a search for the fourth and subsequent cycles)

**NOTE**

The memory addresses of P and Q blocks stored during rough cutting cycles by G71, G72, and G73 are erased after execution of G70. All stored memory addresses of P and Q blocks are also erased by a reset.

- **Return to the cycle start point**

In a finishing cycle, after the tool cuts the workpiece to the end point of the target figure, it returns to the cycle start point in rapid traverse.

**NOTE**

The tool returns to the cycle start point always in the nonlinear positioning mode regardless of the setting of bit 1 (LRP) of parameter No. 1401. Before executing a finishing cycle for a target figure with a pocket cut by G71 or G72, check that the tool does not interfere with the workpiece when returning from the end point of the target figure to the cycle start point.

- **Tool nose radius compensation**

Like G71, this cycle operation is performed according to the figure determined by the tool nose radius compensation path when the offset vector is 0 at start point A and start-up is performed in a block between path A-A'.
Example

Stock removal in facing (G72)

(Diameter designation for X axis, metric input)

N011    G50 X220.0 Z190.0 ;
N012    G00 X176.0 Z132.0 ;

<td>Not required</td>
</tr>
</tbody>
</table>

- Tool nose radius compensation

Tool nose radius compensation cannot be applied.
6.4.7 Multiple Threading Cycle (G76)

The multiple threading cycle can select four cutting methods.

Format

ZpXp-plane

G76 X(U) Z(W) l(i) K(k) D(Δd) A(a) F(L) P(p) Q(q) ;

YpZp-plane

G76 Y(V) Z(W) J(k) K(i) D(Δd) A(a) F(L) P(p) Q(q) ;

XpYp-plane

G76 X(U) Y(V) I(k) J(i) D(Δd) A(a) F(L) P(p) Q(q) ;

X_ Z_ : Coordinates of the cutting end point (point D in the figure) in the direction of the length

U_ W_ : Travel distance to the cutting end point (point D in the figure) in the direction of the length

a : Angle of tool nose

From 0 to 120 in steps of 1 degree

(The default is 0.)

i : Taper amount

If i = 0, ordinary straight threading can be made.

k : Height of thread

Δd : Depth of cut in 1st cut

L : Lead of thread

p : Cutting method (one-edge threading with constant cutting amount by default or for P0)

P1: One-edge threading with constant cutting amount

P2: Both-edge zigzag threading with constant cutting amount

P3: One-edge threading with constant depth of cut

P4: Both-edge zigzag threading with constant depth of cut

q : Threading start angle shift

(From 0 to 360 degrees in steps of 0.001 degrees)

NOTE
1 Even if pocket calculator type decimal point programming is specified (DPI (bit 0 of parameter No. 3401) = 1), the unit of address D is least input increment. In addition, when a decimal point is input in address D, the alarm (PS0007) is issued.
2 A decimal point included in address A has no meaning. That is, A120. is equivalent to A120 in specifying 120 degrees.
3 To use P2, P3, or P4 as a cutting method, the option for multiple repetitive canned cycle II is required.
4 Address Q does not allow decimal point input.
### 6. MEMORY OPERATION

**Fig. 6.4.7 (a) Cutting path in multiple threading cycle**

\[
r: \text{Amount of thread chamfering (parameter No.5130)}
\]
Explanation
- Operations

This cycle performs threading so that the length of the lead only between C and D is made as specified in the F code. In other sections, the tool moves in rapid traverse. The time constant for acceleration/deceleration after interpolation and FL feedrate for thread chamfering and the feedrate for retraction after chamfering are the same as for thread chamfering with canned cycle.

⚠️ CAUTION

Notes on threading are the same as those on G32 threading. For feed hold in a threading cycle, however, see "Feed hold in a threading cycle" described below.

- Cutting method

There are four cutting methods.

Fig. 6.4.7 (b) One-edge threading with constant cutting amount, both-edge zigzag threading with constant cutting amount (P1/2)

Fig. 6.4.7 (c) One-edge threading with constant depth of cut, both-edge zigzag threading with constant depth of cut (P3/4)
- Repetitive count in finishing

The last finishing cycle (cycle in which the finishing allowance is removed by cutting) is repeated. The repetitive count is set in parameter No. 5142. If the setting is 0, the operation is performed once.

- Minimum depth of cut

When a cutting method with constant cutting amount is selected (P1 or P2), clamping can be performed with the minimum depth of cut to prevent the depth of cut from becoming too small. The minimum depth of cut is set in parameter No. 5140.

<table>
<thead>
<tr>
<th>No.</th>
<th>Unit</th>
<th>Diameter/radius programming</th>
<th>Sign</th>
</tr>
</thead>
<tbody>
<tr>
<td>5140</td>
<td></td>
<td>Depends on the increment system for the reference axis.</td>
<td>Radius programming</td>
</tr>
</tbody>
</table>

- Finishing allowance

The finishing allowance is set in parameter No. 5141.

<table>
<thead>
<tr>
<th>No.</th>
<th>Unit</th>
<th>Diameter/radius programming</th>
<th>Sign</th>
</tr>
</thead>
<tbody>
<tr>
<td>5141</td>
<td></td>
<td>Depends on the increment system for the reference axis.</td>
<td>Radius programming</td>
</tr>
</tbody>
</table>
- Relationship between the sign of the taper amount and tool path

The signs of incremental dimensions for the cycle shown in Fig. 6.4.7 (a) are as follows:

Cutting end point in the direction of the length for U and W:

Minus (determined according to the directions of paths A-C and C-D)

Taper amount (i):

Minus (determined according to the direction of path A-C)

Height of thread (k):

Plus (always specified with a plus sign)

Depth of cut in the first cut ($\Delta d$):

Plus (always specified with a plus sign)

The four patterns shown in the table below are considered corresponding to the sign of each address. A female thread can also be machined.

<table>
<thead>
<tr>
<th>Outer diameter machining</th>
<th>Internal diameter machining</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. $U &lt; 0, W &lt; 0, i &lt; 0$</td>
<td>2. $U &gt; 0, W &lt; 0, i &gt; 0$</td>
</tr>
</tbody>
</table>

- Acceleration/deceleration after interpolation for threading

Acceleration/deceleration after interpolation for threading is acceleration/deceleration of exponential interpolation type. By setting bit 5 (THLx) of parameter No. 1610, the same acceleration/deceleration as for cutting feed can be selected. (The settings of bit 0 (CTLx) of parameter No. 1610 are followed.) However, as a time constant and FL feedrate, the settings of parameter No. 1626 and No. 1627 for the threading cycle are used.
- **Time constant and FL feedrate for threading**

The time constant for acceleration/deceleration after interpolation for threading specified in parameter No. 1626 and the FL feedrate specified in parameter No. 1627 are used.

- **Thread chamfering**

Thread chamfering can be performed in this threading cycle. A signal from the machine tool initiates thread chamfering.

The maximum amount of thread chamfering (r) can be specified in a range from 0.1L to 12.7L in 0.1L increments in parameter No. 5130. A thread chamfering angle between 1 to 89 degrees can be specified in parameter No. 5131. When a value of 0 is specified in the parameter, an angle of 45 degrees is assumed.

For thread chamfering, the same type of acceleration/deceleration after interpolation, time constant for acceleration/deceleration after interpolation, and FL feedrate as for threading are used.

**NOTE**

Common parameters for specifying the amount and angle of thread chamfering are used for this cycle and G92 threading cycle.

- **Retraction after chamfering**

The following table lists the feedrate, type of acceleration/deceleration after interpolation, and time constant of retraction after chamfering.

<table>
<thead>
<tr>
<th>Parameter CFR (No. 1611#0)</th>
<th>Parameter No. 1466</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Other than 0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and retraction feedrate specified in parameter No. 1466.</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>Uses the type of acceleration/deceleration after interpolation for threading, time constant for threading (parameter No. 1626), FL feedrate (parameter No. 1627), and rapid traverse rate specified in parameter No. 1420.</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Before retraction a check is made to see that the specified feedrate has become 0 (delay in acceleration/deceleration is 0), and the type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant and the rapid traverse rate (parameter No. 1420).</td>
</tr>
</tbody>
</table>

By setting bit 4 (ROC) of parameter No. 1403 to 1, rapid traverse override can be disabled for the feedrate of retraction after chamfering.
- Shifting the start angle

Address Q can be used to shift the start angle of threading. The start angle (Q) increment is 0.001 degrees and the valid setting range is between 0 and 360 degrees. No decimal point can be specified.

- Feed hold when the threading cycle retract function is used

Feed hold may be applied during threading in a multiple threading cycle (G76). In this case, the tool quickly retracts in the same way as for the last chamfering in a threading cycle and returns to the start point in the current cycle (position where the workpiece is cut by Δdn). When cycle start is triggered, the multiple threading cycle resumes.

![Diagram of threading cycle](image)

The angle of chamfering during retraction is the same as that of chamfering at the end point.

⚠️ **CAUTION**

Feed hold operation during retraction is disabled.

- Inch threading

Inch threading specified with address E is allowed.

- Tool nose radius compensation

Tool nose radius compensation cannot be applied.
Example

G00 X80.0 Z130.0;
G76 X60.64 Z25.0 K3680 D1800 A60 P1 F6.0;
Parameter No.5130 = 10(1.0L)
6.4.8 Restrictions on Multiple Repetitive Canned Cycle

Programmed commands
- Program memory

Programs using G70, G71, G72, or G73 must be stored in the program memory. The use of the mode in which programs stored in the program memory are called for operation enables these programs to be executed in other than the MEM mode. Programs using G74, G75, or G76 need not be stored in the program memory.

- Blocks in which data related to a multiple repetitive canned cycle is specified

The addresses P, Q, X, Z, U, W, and R should be specified correctly for each block.

In a block in which G70, G71, G72, or G73 is specified, the following functions cannot be specified:
- Custom macro calls
  (simple call, modal call, and subprogram call)

- Blocks in which data related to a target figure is specified

In the block which is specified by address P of a G71, G72 or G73, G00 or G01 code in group 01 should be commanded. If it is not commanded, alarm PS0065 is generated.

In blocks with sequence numbers between those specified at P and Q in G70, G71, G72, and G73, the following commands can be specified:
- Dwell (G04)
- G00, G01, G02, and G03
  When a circular interpolation command (G02, G03) is used, there must be no radius difference between the start point and end point of the arc. If there is a radius difference, the target finishing figure may not be recognized correctly, resulting in a cutting error such as excessive cutting.
- Custom macro branch and repeat command
  The branch destination must be between the sequence numbers specified at P and Q, however. High-speed branch specified by bits 1 and 4 of parameter No. 6000 is invalid. No custom macro call (simple, modal, or subprogram call) cannot be specified.
- Direct drawing dimension programming command and chamfering and corner R command
  Direct drawing dimension programming and chamfering and corner R require multiple blocks to be specified. The block with the last sequence number specified at Q must not be an intermediate block of these specified blocks.

When G70, G71, G72, or G73 is executed, the sequence number specified by address P and Q should not be specified twice or more in the same program.

When #1 = 2500 is executed using a custom macro, 2500.000 is assigned to #1. In such a case, P#1 is equivalent to P2500.
Relation with other functions
- Manual intervention
  While a multiple repetitive canned cycle (G70 to G76) is being executed, it is possible to stop the cycle and to perform manual intervention. The setting of manual absolute on or off is effective for manual operation.

- Interruption type macro
  Any interruption type macro program cannot be executed during execution of a multiple repetitive canned cycle.

- Program restart and tool retract and recover
  These functions cannot be executed in a block in a multiple repetitive canned cycle.

- Axis name and second auxiliary functions
  Even if address U, V, W, or A is used as an axis name or second auxiliary function, data specified at address U, V, W, or A in a G71 to G73 or G76 block is assumed to be that for the multiple repetitive canned cycle.

- Tool nose radius compensation
  When using tool nose radius compensation, specify a tool nose radius compensation command (G41, G42) before a multiple repetitive canned cycle command (G70, G71, G72, G73) and specify the cancel command (G40) outside the blocks (from the block specified with P to the block specified with Q) specifying a target finishing figure.
6.5 CANNED CYCLE FOR DRILLING

Canned cycles for drilling make it easier for the programmer to create programs. With a canned cycle, a frequently-used machining operation can be specified in a single block with a G function; without canned cycles, more than one block is required. In addition, the use of canned cycles can shorten the program to save memory. Table 6.5 (a) lists canned cycles for drilling.

</table>

**Explanation**

The canned cycle for drilling consists of the following six operation sequences.

- **Operation 1** ....... Positioning of X and Z axis (Another axis may be targeted.)
- **Operation 2** ....... Rapid traverse up to point R level
- **Operation 3** ....... Hole machining
- **Operation 4** ....... Operation at the bottom of a hole
- **Operation 5** ....... Retraction to point R level
- **Operation 6** ....... Rapid traverse up to the initial level
- Positioning plane

A positioning plane is determined by plane selection with G17, G18, and G19.
The axes other than the drilling axis are used as positioning axes.

- Drilling axis

Although canned cycles include tapping and boring cycles as well as drilling cycles, in this chapter, only the term drilling will be used to refer to operations implemented with canned cycles.
The basic axis (X, Y, or Z) that does not exist on the positioning plane or its parallel axis is used as the drilling axis.
The axis address of the drilling axis specified in the same block as the G codes (G81 to G89) determines whether a basic axis or one of parallel axes is used as the drilling axis.
If the axis address of the drilling axis is not specified, the basic axis is used as the drilling axis.

<table>
<thead>
<tr>
<th>Table 6.5 (b) Positioning plane and drilling axis</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>G code</strong></td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>G17</td>
</tr>
<tr>
<td>G18</td>
</tr>
<tr>
<td>G19</td>
</tr>
</tbody>
</table>

Xp : X axis or its parallel axis
Yp : Y axis or its parallel axis
Zp : Z axis or its parallel axis
- Example

Suppose parameter No. 1022 is set so that U, V, and W are the parallel axes of X, Y, and Z, respectively.

\[
\begin{align*}
G17 & \ G81 \quad Z\_\_\_: \text{Drilling axis is } Z \text{ axis.} \\
G17 & \ G81 \quad W\_\_\_: \text{Drilling axis is } W \text{ axis.} \\
G18 & \ G81 \quad Y\_\_\_: \text{Drilling axis is } Y \text{ axis.} \\
G18 & \ G81 \quad V\_\_\_: \text{Drilling axis is } V \text{ axis.} \\
G19 & \ G81 \quad X\_\_\_: \text{Drilling axis is } X \text{ axis.} \\
G19 & \ G81 \quad U\_\_\_: \text{Drilling axis is } U \text{ axis.}
\end{align*}
\]

G17, G18, and G19 may be specified in a block in which G73 to G89 are not present.

⚠️ CAUTION

Before switching between drilling axes, cancel canned cycles.

NOTE

The Z-axis can always be used as the drilling axis by setting FXY (bit 0 of parameter No. 5101). When FXY is 0, the Z-axis is always used as the drilling axis.

- Specification of point R

In the Series 0i command format, the distance from the initial level to point R is specified using an incremental value during specification of point R.

In the Series 10/11 command format, the specification method depends on RAB (bit 6 of parameter No. 5102). When RAB = 0, an incremental value is always used for specification. When RAB = 1 for G code system A, an absolute value is used for specification. When RAB = 1 for G code system B, C, an absolute value is used in G90 mode while an incremental value is used in G91 mode.

<table>
<thead>
<tr>
<th></th>
<th>Series 10/11 command format</th>
<th>Series 0i command format</th>
</tr>
</thead>
<tbody>
<tr>

<td>Incremental</td>
</tr>
<tr>
<td>A</td>
<td>G90</td>
<td>G91</td>
</tr>
<tr>
<td>Absolute</td>
<td>Absolute Incremental</td>
<td></td>
</tr>
</tbody>
</table>

- Diameter/radius programming

The diameter/radius specification of canned cycles for drilling R command in the series 10/11 command format can be matched with the diameter/radius specification of the drilling axis by setting RDI (bit 7 of parameter No. 5102) to 1.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

- **P**

In the following G codes, dwell operation differs between Series 10/11 and Series 10/11.

Operation of this CNC using the Series 10/11 format
In G83, G83.1, G84, and G84.2, dwelling is performed only when address P is specified in a block.

Operation of Series 10/11
In G83 and G83.1, dwelling is not performed.
In G84 and G84.2, dwelling with address P can be performed by setting DWL (bit 1 of parameter No.6200). Address P is modal data.

- **Q**

Address Q is always specified by using an incremental value during specification of a radius.

- **Feedrate for G85 and G89**

In G85 and G89, the feedrate from point Z to point R is double the cutting feedrate. For Series 10/11, it is the same as the cutting feedrate.

- **Drilling mode**

G81 to G89 are modal G codes and remain in effect until canceled. When in effect, the current state is the drilling mode.
Once drilling data is specified in the drilling mode, the data is retained until modified or canceled.
Specify all necessary drilling data at the beginning of canned cycles; when canned cycles are being performed, specify data modifications only.
- Return point level G98/G99

In G code system A, the tool returns to the initial level from the bottom of a hole. In G code system B or C, specifying G98 returns the tool to the initial level from the bottom of a hole and specifying G99 returns the tool to the point-R level from the bottom of a hole.

The following illustrates how the tool moves when G98 or G99 is specified. Generally, G99 is used for the first drilling operation and G98 is used for the last drilling operation.

The initial level does not change even when drilling is performed in the G99 mode.

- Number of repeats

To repeat drilling for equally-spaced holes, specify the number of repeats in \( L \).

\( L \) is effective only within the block where it is specified.

Specify the first hole position in incremental mode.

If it is specified in absolute mode, drilling is repeated at the same position.

<table>
<thead>
<tr>
<th>Number of repeats ( L )</th>
<th>The maximum command value = 9999</th>
</tr>
</thead>
</table>

When \( L0 \) is specified, drilling data is just stored without drilling being performed.

**NOTE**

For \( L \), specify an integer of 0 or 1 to 9999.

- C axis clamp

The M code for C axis clamp can be specified in the Series 0i command format, but it cannot be specified in the Series 10/11 command format.
6. MEMORY OPERATION
USING Series 10/11 FORMAT
PROGRAMMING

- Disabling the Series 10/11 format

The Series 10/11 command format can be disabled only during a canned cycle for drilling by setting F0C (bit 3 of parameter No.5102) to 1. However, the repetitive count must be specified by address L.

⚠️ CAUTION
If F16 (bit 3 of parameter No.5102) is set to 1, the settings of RAB (bit 6 of No.5102) and RDI (bit 7 of No.5102) are disabled, and operation when RAB=0 and RDI=0 is performed.

- Cancel

To cancel a canned cycle, use G80 or a group 01 G code.

Group 01 G codes (Example)
G00 : Positioning (rapid traverse)
G01 : Linear interpolation
G02 : Circular interpolation (CW) or helical interpolation (CW)
G03 : Circular interpolation (CCW) or helical interpolation (CCW)

- Symbols in figures

Subsequent subsections explain the individual canned cycles. Figures in these explanations use the following symbols:

- → Positioning (rapid traverse G00)
- → Cutting feed (linear interpolation G01)
P Dwell
6.5.1 Drilling Cycle, Spot Drilling Cycle (G81)

The normal drilling cycle is used. The tool is then retracted from the bottom of the hole in rapid traverse.

Format

```
G81 X_ Y_ Z_ R_ F_ L_;  
X_ Y_ : Hole position data
Z_ : The distance from point R to the bottom of the hole
R_ : The distance from the initial level to point R level
F_ : Cutting feedrate
L_ : Number of repeats (When it is needed.)
```

<table>
<thead>
<tr>
<th>G81 (G98 mode)</th>
<th>G81 (G99 mode)</th>
</tr>
</thead>
</table>

- **Operations**

Rapid traverse to the point R level is performed after positioning of the X- and Y- axes. Then, drilling is performed from point R level to point Z. Escaping moves in rapid traverse.

- **Spindle rotation**

Before specifying G81, use an auxiliary function (M code) to rotate the spindle.

- **Auxiliary function**

If the G81 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

Limitation

- Axis switching

Before switching between drilling axes, cancel canned cycles for drilling.

- Drilling

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- Cancel

The G codes (G00 to G03) in group 01 must not be specified in the block in which G81 is specified. This cancels G81.
6.MEMORY OPERATION
USING Series 10/11 FORMAT

6.5.2 Drilling Cycle, Counter Boring (G82)

The normal drilling cycle is used. Cutting feed is performed to the bottom of the hole, dwelling is performed at the bottom, and then escaping from the bottom is performed in rapid traverse.

The accuracy of the hole depth is improved.

Format

\[
\text{G82 X}_n \text{ Y}_n \text{ Z}_n \text{ R}_n \text{ P}_n \text{ F}_n \text{ L}_n ;
\]

- **X**, **Y**: Hole position data
- **Z**: The distance from point R to the bottom of the hole
- **R**: The distance from the initial level to point R level
- **P**: Dwell time at the bottom of a hole
- **F**: Cutting feedrate
- **L**: Number of repeats (When it is needed.)

G81 (G98 mode)  |  G81 (G99 mode)
--- | ---
Initial level | Initial level
Point R | Point R
Point Z | Point Z
Point R level | Point R level

Explanation

- Operations

Rapid traverse to the point R level is performed after positioning of the X- and Y- axes.
Then, drilling is performed from point R level to point Z.
Dwelling is performed at the bottom of the hole and then escaping is performed in rapid traverse.

- Spindle rotation

Before specifying G82, use an auxiliary function (M code) to rotate the spindle.

- Auxiliary function

If the G82 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.
Limitation

- **Axis switching**
  Before switching between drilling axes, cancel canned cycles for drilling.

- **Drilling**
  In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- **P**
  P must be specified in a block in which drilling is instructed. Otherwise, data is not stored as modal data.

- **Cancel**
  The G codes (G00 to G03) in group 01 must not be specified in the block in which G82 is specified. This cancels G82.
6.5.3 Peck Drilling Cycle (G83)

Peck drilling is performed. Cutting feed is performed intermittently to the bottom of the hole while chips are discharged.

Format

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G83 X_ Y_ Z_ R_ P_ Q_ F_ L_;</td>
<td></td>
</tr>
<tr>
<td>X_ Y_</td>
<td>Hole position data</td>

<tr>
<td>Z_</td>
<td>The distance from point R to the bottom of the hole</td>
</tr>
<tr>
<td>R_</td>
<td>The distance from the initial level to point R level</td>
</tr>
<tr>
<td>P_</td>
<td>Dwell time</td>
</tr>
<tr>
<td>Q_</td>
<td>Depth of cut for each cutting feed</td>
</tr>
<tr>
<td>F_</td>
<td>Cutting feedrate</td>
</tr>
<tr>
<td>L_</td>
<td>Number of repeats (When it is needed.)</td>
</tr>
</tbody>
</table>

G83 (G98 mode)  G83 (G99 mode)

Explanation

- Operations

Q indicates the depth of cut for each operation and is specified by an incremental value.
In the second and later cutting operations, rapid traverse is changed to cutting feed at the point distance "d" back from the previously drilled position. "d" is set in parameter No. 5115.
A positive value must be specified for Q. A negative value is ignored.

- Spindle rotation

Before specifying G83, use an auxiliary function (M code) to rotate the spindle.

- Auxiliary function

If the G83 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

Limitation
- Axis switching
Before switching between drilling axes, cancel canned cycles for drilling.

- Drilling
In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- P
Dwelling is performed only when address P is specified in a block.

- Q
Q must be specified in a block in which drilling is instructed. Otherwise, data is not stored as modal data.

- Cancel
The G codes (G00 to G03) in group 01 must not be specified in the block in which G83 is specified. This cancels G83.
6.5.4 High-speed Peck Drilling Cycle (G83.1)

This cycle performs high-speed peck drilling. It performs cutting feed intermittently while discharging chips.

Format

G83.1 X_ Y_ Z_ R_ P_ Q_ F_ L_ ;
X_ Y_ : Hole position data
Z_ : The distance from point R to the bottom of the hole
R_ : The distance from the initial level to point R level
P_ : Dwell time
Q_ : Depth of cut for each cutting feed
F_ : Cutting feedrate
L_ : Number of repeats (When it is needed)

G83.1 (G98 mode)  
G83.1 (G99 mode)

Explanation

- Operations

Since intermittent feed in the Z-axis direction makes discharge of chips easier and allows the fine setting of the escaping amount, efficient machining can be performed.
Escape amount d is set in parameter No. 5114.
Escaping moves in rapid traverse.

- Spindle rotation

Before specifying G83.1, use an auxiliary function (M code) to rotate the spindle.
6. MEMORY OPERATION
USING Series 10/11 FORMAT  PROGRAMMING B-64304EN-1/01

- **Auxiliary function**

If the G83.1 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>- <strong>Axis switching</strong></td>
</tr>
</tbody>
</table>

Before switching between drilling axes, cancel canned cycles for drilling.

| - **Drilling** |

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

| - **P** |

Dwelling is performed only when address P is specified in a block.

| - **Q** |

Q must be specified in a block in which drilling is instructed. Otherwise, data is not stored as modal data.

| - **Cancel** |

The G codes (G00 to G03) in group 01 must not be specified in the block in which G83.1 is specified. This cancels G83.1.
6.5.5 Tapping Cycle (G84)

This cycle performs tapping. In this tapping cycle, when the bottom of the hole has been reached, the spindle is rotated in the reverse direction.

Format

G84 X_ Y_ Z_ R_ P_ F_ L_ ;

- X_ Y_: Hole position data
- Z_: The distance from point R to the bottom of the hole
- R_: The distance from the initial level to point R level
- P_: Dwell time
- F_: Cutting feedrate
- L_: Number of repeats (When it is needed.)

<table>
<thead>
<tr>
<th>G84 (G98 mode)</th>
<th>G84 (G99 mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Diagram 1]</td>
<td>![Diagram 2]</td>
</tr>
</tbody>
</table>

Explanation

- Operations

Tapping is performed by rotating the spindle clockwise.

⚠️ CAUTION

Feedrate override is ignored during tapping. In addition, applying feed hold does not stop the machine until return operation is completed.

- Spindle rotation

Before specifying G84, use an auxiliary function (M code) to rotate the spindle.

When drilling in which the distance from the hole position and initial level to the point R level is short is continuously performed, the spindle may not reach the normal speed by the time cutting operation for the hole is ready to be performed. In this case, reserve a time by inserting dwelling by G04 before each drilling operation without specifying repetitive count L.

Since this consideration may not be required depending on the machine type, refer to the manual issued by the machine tool builder.
6. MEMORY OPERATION USING Series 10/11 FORMAT PROGRAMMING

- Auxiliary function

If the G84 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.

Limitation

- Axis switching

Before switching between drilling axes, cancel canned cycles for drilling.

- Drilling

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- P

Dwelling is performed only when address P is specified in a block.

- Cancel

The G codes (G00 to G03) in group 01 must not be specified in the block in which G84 is specified. This cancels G84.

NOTE

Set M5T (bit 6 of parameter No. 5101) to specify whether the spindle stop command (M05) is specified before the command for rotating the spindle in the forward or reverse direction (M03 or M04) is specified.

For details, refer to the manual issued by the machine tool builder.
6.5.6 Tapping Cycle (G84.2)

Controlling the spindle motor in the same way as a servo motor executes the high-speed tapping cycle.

Format

\[ \text{G84.2 X\_ Y\_ Z\_ R\_ P\_ F\_ L\_ S\_;} \]

- \text{X\_ Y\_} : Hole position data
- \text{Z\_} : The distance from point R to the bottom of the hole
- \text{R\_} : The distance from the initial level to point R level
- \text{P\_} : Dwell time
- \text{F\_} : Cutting feedrate
- \text{L\_} : Number of repeats (When it is needed.)
- \text{S\_} : Spindle speed

G84.2 (G98 mode) | G84.2 (G99 mode)
--- | ---
![Diagram showing the tapping cycle process with labels for spindle stop, initial level, point R, point Z, spindle CW, spindle CCW.]

A G code cannot discriminate between the front face tapping cycle and side face tapping cycle using Series 10/11 format commands. The drilling axis is determined by plane selection (G17, G18, or G19). Specify the plane selection that becomes equivalent to the front face tapping cycle or side face tapping cycle as appropriate. (When bit 0 (FXY) of parameter No. 5101 is set to 0, the Z-axis is used as the drilling axis. When the bit is set to 1, plane selection is as follows.)

<table>
<thead>
<tr>
<th>Plane selection</th>
<th>Drilling axis</th>
</tr>
</thead>
<tbody>
<tr>
<td>G17 Xp-Yp plane</td>
<td>Zp</td>
</tr>
<tr>
<td>G18 Zp-Xp plane</td>

</tr>
<tr>
<td>G19 Yp-Zp plane</td>
<td>Xp</td>
</tr>
</tbody>
</table>

Xp: X-axis or an axis parallel to it
Yp: Y-axis or an axis parallel to it
Zp: Z-axis or an axis parallel to it
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

Explanation
- Operations

The tool is positioned along the X- and Y-axes, then moves to the point R level in rapid traverse. Tapping is performed from the point R level to point Z, after which the spindle stops and the tool dwells. Then, the spindle starts reverse rotation, the tool is retracted to the point R level, and the spindle stops. After that, when G98 is specified, the tool moves to the initial level in rapid traverse. During tapping, the feedrate override and spindle override are assumed to be 100%. For retraction (operation 5), however, a fixed override of up to 2000% can be applied by setting bit 4 (DOV) of parameter No. 5200, bit 3 (OVU) of parameter No. 5201, and parameter No. 5211.

- Thread lead

In the feed per minute mode, feedrate ÷ spindle speed = thread lead. In the feed per rotation mode, feedrate = thread lead.

Limitation
- Axis switching

Before switching between drilling axes, cancel canned cycles for drilling. If the drilling axis is changed in the rigid mode, alarm PS0206 is issued.

- Drilling

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- P

Dwelling is performed only when address P is specified in a block.

- Cancel

The G codes (G00 to G03) in group 01 must not be specified in the block in which G84.2 is specified. This cancels G84.2.

- Tool offset

In the canned cycle mode, tool offsets are ignored.
6.5.7 Boring Cycle (G85)

This cycle is used to bore a hole.

**Format**

\[
\text{G85 X}_n \text{ Y}_n \text{ Z}_n \text{ R}_n \text{ F}_n \text{ L}_n ;
\]

- **X**, **Y**: Hole position data
- **Z**: The distance from point R to the bottom of the hole
- **R**: The distance from the initial level to point R level
- **F**: Cutting feedrate
- **L**: Number of repeats (When it is needed.)

**G85 (G98 mode) vs G85 (G99 mode)**

**Explanation**

- **Operations**
  
  Rapid traverse to the point R level is performed after positioning of the X- and Y- axes.
  Then, drilling is performed from point R level to point Z.
  After reaching point Z, return to point R in cutting feed.

- **Spindle rotation**
  
  Before specifying G85, use an auxiliary function (M code) to rotate the spindle.

- **Auxiliary function**
  
  If the G85 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.
6. MEMORY OPERATION
USING Series 10/11 FORMAT

PROGRAMMING

Limitation
- Axis switching

Before switching between drilling axes, cancel canned cycles for drilling.

- Drilling

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- Cancel

The G codes (G00 to G03) in group 01 must not be specified in the block in which G85 is specified. This cancels G85.
6.5.8 Boring Cycle (G89)

This cycle is used to bore a hole.

Format

G89 X_ Y_ Z_ R_ P_ F_ L_;  
X_ Y_ : Hole position data  
Z_ : The distance from point R to the bottom of the hole  
R_ : The distance from the initial level to point R level  
P_ : Dwell time at the bottom of a hole  
F_ : Cutting feedrate  
L_ : Number of repeats (When it is needed.)

<table>
<thead>
<tr>
<th>G89 (G98 mode)</th>
<th>G89 (G99 mode)</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Diagram" /></td>
<td><img src="image2.png" alt="Diagram" /></td>
</tr>
</tbody>
</table>

Explanation

- **Operations**
  This is the same as G85, but dwelling is performed at the bottom of the hole.

- **Spindle rotation**
  Before specifying G89, use an auxiliary function (M code) to rotate the spindle.

- **Auxiliary function**
  If the G89 command and an M code are specified in the same block, the M code is executed at the first positioning. When repetitive count L is specified, the operation above is performed for the first time and the M code is not performed second and later times.
6. MEMORY OPERATION

USING Series 10/11 FORMAT

PROGRAMMING

B-64304EN-1/01

Limitation

- Axis switching

Before switching between drilling axes, cancel canned cycles for drilling.

- Drilling

In a block that does not include X, Y, Z, R, or an additional axis, drilling is not performed.

- P

P must be specified in a block in which drilling is instructed. Otherwise, data is not stored as modal data.

- Cancel

The G codes (G00 to G03) in group 01 must not be specified in the block in which G89 is specified. This cancels G89.
6.5.9 Canned Cycle for Drilling Cancel (G80)

G80 cancels canned cycle for drilling.

<table>
<thead>
<tr>
<th>Format</th>
<th>G80 ;</th>
</tr>
</thead>
</table>

Explanation
Canned cycle for drilling is canceled to perform normal operation.
Point R and point Z are cleared.
Other drilling data is also canceled (cleared).

6.5.10 Precautions to be Taken by Operator

- Reset and emergency stop
Even when the controller is stopped by resetting or emergency stop in the course of drilling cycle, the drilling mode and drilling data are saved; with this mind, therefore, restart operation.

- Single block
When drilling cycle is performed with a single block, the operation stops at the end points of operations 1, 2, 6 in Fig. 6.5 (a). Consequently, it follows that operation is started up 3 times to drill one hole. The operation stops at the end points of operations 1, 2 with the feed hold lamp ON. If there is a remaining repetitive count at the end of operation 6, the operation is stopped by feed hold. If there is no remaining repetitive count, the operation is stopped in the single block stop state.

- Feed hold
When "Feed Hold" is applied between operations 3 and 5 by G84/G88, the feed hold lamp lights up immediately if the feed hold is applied again to operation 6.

- Override
During operation with G84 and G88, the feedrate override is 100%.
7. AXIS CONTROL FUNCTIONS

Chapter 7, "AXIS CONTROL FUNCTIONS", consists of the following sections:

7.1 POLYGON TURNING (G50.2, G51.2).................................339
7.2 SYNCHRONOUS, COMPOSITE AND SUPERIMPOSED CONTROL BY PROGRAM COMMAND (G50.4, G51.4, G50.5, G51.5, G50.6, AND G51.6).................................345
7.1 POLYGON TURNING (G50.2, G51.2)

Polygon turning means machining a workpiece to a polygonal figure by rotating the workpiece and tool at a certain ratio.

By changing conditions which are rotation ratio of workpiece and tool and number of cutters, the workpiece can be machined to a square or hexagon. The machining time can be reduced as compared with polygonal figure machining using the polar coordinate interpolation. The machined figure, however, is not exactly polygonal. Generally, polygon turning is used for the heads of square and/or hexagon bolts or hexagon nuts.

As the tool rotary axis, one of the following can be used:

- CNC controlled axis (servo axis)
- Second spindle (Two serial spindles are connected.)

Polygonal machining performed using a servo axis as the tool rotary axis is referred to as polygon turning. Polygonal machining performed using the second spindle as the tool rotary axis is referred to as polygon turning with two spindles.

<td>Spindle</td>
</tr>
<tr>
<td>spindles</td>
<td>(Serial spindle)</td>
<td>(Serial spindle)</td>
</tr>
</tbody>
</table>
Explanation

A CNC controlled axis (servo axis) is assigned to the tool rotary axis. This rotary axis of tool is called Y-axis in the following description. As the workpiece axis (spindle), either a serial spindle or analog spindle can be used.

The Y-axis is controlled by the G51.2 command, so that the ratio of the rotation speeds of the spindle (previously specified by S-command) and the tool becomes the specified ratio.

When simultaneous start is specified by G51.2, the one-rotation signal sent from the position codes set on the spindle is detected. After one-rotation signal detection, the Y-axis is controlled using the rotation ratio of the spindle and Y-axis specified by P and Q. So, a position coder needs to be attached to the spindle. This control will be maintained until the polygon turning cancel command is executed (G50.2). Polygon turning is cancelled by any of the following in addition to the G50.2 command:

1. Power off
2. Emergency stop
3. Servo alarm
4. Reset (external reset signal ERS, reset/rewind signal RRW, and RESET key on the MDI panel)
5. Occurrence of alarms PS0217 to PS0221, PS0314, and PS05018

NOTE

1. Before polygon turning, reference position return operation on the Y-axis needs to be specified to determine the rotation start position of the tool. This reference position return operation is performed by detecting a deceleration limit as in the case of manual reference position return operation. (By setting bit 7 (PLZ) of parameter No. 7600, reference position return operation can be performed without detecting a deceleration limit.)
2. The rotation direction on the Y-axis is determined by the sign of Q, and is not affected by the rotation direction of the position coder.
3. Among the current position display of the Y axis, the display for the machine coordinate value (MACHINE) changes from a range of 0 to the amount of movement per revolution as the Y axis moves. Absolute and relative coordinate values are not updated. So, when specifying an absolute programming for the Y-axis after polygon turning mode cancellation, set a workpiece coordinate system after reference position return operation.
NOTE
4 For the Y-axis engaged in polygon turning, jog feed and handle feed are disabled.
5 For the Y-axis not engaged in polygon turning, a move command can be specified as in the case of other controlled axes.
6 The Y-axis engaged in polygon turning is not counted in the number of simultaneously controlled axes.
7 One workpiece must be machined using a fixed spindle speed until the workpiece is finished.
8 Polygon turning with two spindles cannot be used at the same time.
9 G50.2 is the G code for suppressing buffering.

⚠️ CAUTION
1 During polygon turning, threading cannot be performed.
2 For the Y-axis engaged in synchronous operation, the signals below are valid or invalid:
   Signals valid for the Y-axis
   • Machine lock
   • Servo-off
   Signals invalid for the Y-axis
   • Feed hold
   • Interlock
   • Override
   • Dry run
   (At dry run time, however, the one-rotation signal is not awaited in a G51.2 block.)
7. AXIS CONTROL FUNCTIONS  PROGRAMMING  B-64304EN-1/01

Format

<table>

</tr>
</tbody>
</table>

**NOTE**
Specify G50.2 and G51.2 in a single block.

Example

```
G00 X100.0 Z20.0 S1000.0 M03 ;  (Workpiece rotation speed 1000 (min⁻¹))
G51.2 P1 Q2 ;  (Tool rotation start (tool rotation speed 2000 (min⁻¹))
G01 X80.0 F10.0 ;  (X-axis in-feed)
G04 X2.0 ;  (Waiting 2 seconds)
G00 X100.0 ;  (X-axis escape)
G50.2 ;  (Tool rotation stop)
M05 S0 ;  (Spindle stop )
```
- Principle of polygon turning

In the figure below the radius of tool and workpiece are A and B, and the angular speeds of tool and workpiece are $\alpha$ and $\beta$. The origin of XY Cartesian coordinates is assumed to be the center of the workpiece.

Simplifying the explanation, consider that the tool center exists at the position $P_o$ (A, 0) on the workpiece periphery, and the tool nose starts from position $P_{to}$ (A-B, 0).

In this case, the tool nose position $P_t (X_t, Y_t)$ after time t is expressed by equations 1 and 2:

\[
X_t = A \cos \alpha t - B \cos (\beta - \alpha) t \quad \text{(Equation 1)}
\]
\[
Y_t = A \sin \alpha t + B \sin (\beta - \alpha) t \quad \text{(Equation 2)}
\]

Assuming that the rotation ration of workpiece to tool is 1:2, namely, $\beta = 2\alpha$, equations 1 and 2 are modified as follows:

\[
X_t = A \cos \alpha t - B \cos \alpha t = (A-B) \cos \alpha t \quad \text{(Equation 1)'}
\]
\[
X_t = A \sin \alpha t + B \sin \alpha t = (A+B) \sin \alpha t \quad \text{(Equation 2)'}
\]

These equations indicate that the tool nose path draws an ellipse with longer diameter A+B and shorter diameter A-B.

Then consider the case when one tool is set at 180° symmetrical positions, for a total of two. A square can be machined with these tools as shown below.
If three tools are set at every 120°, the machining figure will be a hexagon as shown below.

⚠️ **WARNING**
For the maximum rotation speed of the tool, see the instruction manual supplied with the machine. Do not specify a spindle speed higher than the maximum tool speed or a ratio to the spindle speed that results in a speed higher than the maximum tool speed.
7.2 SYNCHRONOUS, COMPOSITE AND SUPERIMPOSED CONTROL BY PROGRAM COMMAND (G50.4, G51.4, G50.5, G51.5, G50.6, AND G51.6)

Synchronous control, composite control, and superimposed control can be started or canceled using a program command instead of a DI signal. Synchronous control, composite control, and superimposed control based on a DI signal is also possible.

For the basic operations of synchronous control, composite control, and superimposed control, see Sections, "SYNCHRONOUS CONTROL AND COMPOSITE CONTROL" and Section, "SUPERIMPOSED CONTROL" in the CONNECTION MANUAL (FUNCTION) (B-64303EN-1).

Format

- Parameter check

If the axis number corresponding to the P specified with G51.6 is not set in superimposed slave axis parameter No. 8186, alarm PS5339 is issued.

NOTE

1. If G codes (G50.4/G50.5/G50.6) for canceling synchronous, composite, and superimposed control with program commands are issued for axes under synchronous, composite, and superimposed control with DI signals, synchronous, composite, and superimposed control is canceled.

2. If the synchronous control axis selection signal, composite control axis selection signal, and superimposed control axis selection signal are changed from '1' to '0' for axes under synchronous, composite, and superimposed control with program commands, synchronous, composite, and superimposed control is canceled.
8

2-PATH CONTROL FUNCTION

Chapter 8, "2-PATH CONTROL FUNCTION", consists of the following sections:

8.1 OVERVIEW.................................................................350
8.2 WAITING FUNCTION FOR PATHS.............................351
8.3 COMMON MEMORY BETWEEN EACH PATH.............352
8.4 SPINDLE CONTROL BETWEEN EACH PATH..............354
8.5 SYNCHRONOUS/COMPOSITE/SUPERIMPOSED
   CONTROL .................................................................355
8.6 BALANCE CUT (G68, G69)........................................358
8.1 OVERVIEW

The 2-path control function is intended to perform two types of machining simultaneously and independently. The function applies to lathes and automatic lathes with which two tool posts operate simultaneously to machine one workpiece.

To control two paths to machine one workpiece simultaneously, the machining program for each path is stored in the program memory for the path. In automatic operation, this function selects the program for path 1 and that for path 2 from the program memory for the relevant path. When the paths are activated, the programs selected for the relevant tool posts are executed simultaneously and independently.

To make tool posts 1 and 2 synchronous during machining, the waiting function can be used.

Other functions specific to 2-path control that include the following functions can also be used: Interference check for each path, balance cutting, synchronous/composite/superimposed control, spindle control between each path, and common memory between each path.

Only one LCD/MDI is provided for two paths. The path selection signal is used to switch LCD/MDI operation or display between paths 1 and 2.

For a system with two paths
8.2 WAITING FUNCTION FOR PATHS

Overview

Control based on M codes is used to cause one path to wait for the other during machining. When an M code for waiting is specified in a block for one path during automatic operation, the another path waits for the same M code to be specified before starting the execution of the next block.

A range of M codes used as M codes for waiting is to be set in the parameters (Nos. 8110 and 8111) beforehand. Waiting can be ignored using a signal.

Format

\[ Mm \;
\]

- \( m \): Number of an M code for waiting

Explanation

⚠️ CAUTION

1. An M code for waiting must always be specified in a single block.
2. Unlike other M codes, the M code for waiting is not output to the PMC.
3. If the operation of a single path is required, the M code for waiting need not be deleted. By using the signal to specify that waiting be ignored (NOWT), the M code for waiting in a machining program can be ignored. For details, refer to the manual supplied by the machine tool builder.
4. If using a waiting M code in 1 block multiple-M code command, be sure to specify it as the first M code.
8.3 COMMON MEMORY BETWEEN EACH PATH

Overview

In a 2-path system, this function enables data within the specified range to be accessed as data common to both paths. The data includes tool compensation memory and custom macro common variables.

Explanation

The path common memory function enables the following operations.

- Tool compensation memory

Part or all of tool compensation memory for individual paths can be used as common data by setting parameter No. 5029.

NOTE

1. The same unit for tool compensation (bits 0 and 1 of parameter No. 5042) must be set for both paths.
2. Set a value less than the number of tool compensation values for each path for parameter No. 5029.
3. When the setting of parameter No. 5029 exceeds the number of tool compensation values for each path, the smaller of the numbers of tool compensation values for both paths is used as a common number.
4. For details, refer to the relevant manual of the machine tool builder.
- Custom macro common variables

All or part of custom macro common variables #100 to #199 and #500 to #999 can be used as common data by setting parameters No. 6036 (#100 to #199) and 6037 (#500 to #999).

NOTE

If the value of parameter No. 6036 or 6037 exceeds the maximum number of custom macro common variables, the maximum number of custom macro common variables is assumed.
8.4 SPINDLE CONTROL BETWEEN EACH PATH

Overview

This function allows a workpiece attached to one spindle to be machined simultaneously with two tool posts and each of two workpieces attached to each of two spindles to be machined simultaneously with each of two tool posts.

The spindle belonging to each path can generally be controlled by programmed commands for the path. With path spindle command selection signals, programmed commands for any path can control the spindle belonging to any path.

NOTE

For the method of spindle command selection, refer to the relevant manual of the machine tool builder.
8.5 SYNCHRONOUS/COMPOSITE/SUPERIMPOSED CONTROL

Overview

In 2-path control, the synchronous control function, composite control function, and superimposed control function enable synchronous control, composite control, and superimposed control in a single path system or between 2-path systems.

Explanation

- Synchronous control

  - Synchronizes movement along an axis of one system with that along an axis of another path.

  Example)
  Synchronizing movement along the Z1 (master) and Z2 (slave) axes

Machining according to a program for path 1
• Synchronizes movement along an axis of one path with that along another axis of the same path.
Example)
Synchronizing movement along the Z1 (master) and B1 (slave) axes

- Composite control

• Exchanges the move commands for different axes of different path.
Example)
Exchanging the commands for the X1 and X2 axes
→ Upon the execution of a command programmed for path 1, movement is performed along the X2 and Z1 axes.
Upon the execution of a command programmed for path 2, movement is performed along the X1 and Z2 axes.
- Superimposed control

- Provides a move command of an axis for a different axis in another path.
  Example) Providing the Z2 (slave) axis with a move command specified for the Z1 (master) axis

![Diagram of superimposed control]

**NOTE**

The method used to specify synchronous, composite, or superimposed control varies with the machine tool builder. For details, refer to the manual supplied by the machine tool builder.
8.6 BALANCE CUT (G68, G69)

Overview

When a thin workpiece is to be machined as shown below, a precision machining can be achieved by machining each side of the workpiece with a tool simultaneously; this function can prevent the workpiece from warpage that can result when only one side is machined at a time (see the figure below). When both sides are machined at the same time, the movement of one tool must be in phase with that of the other tool. Otherwise, the workpiece can vibrate, resulting in poor machining. With this function, the movement of one tool post can be easily synchronized with that of the other tool post.

![Diagram of tool posts](image)

Format

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G68</td>
<td>Balance cut mode on</td>
</tr>
<tr>
<td>G69</td>
<td>Balance cut mode cancel</td>
</tr>
</tbody>
</table>
Explanation

When G68 is specified in the programs for tool posts 1 and 2, the balance cut mode is set to on. When G69 is specified, the balance cut mode is canceled.

When G68 or G69 is specified for either tool post, the tool post waits until G68 or G69 is specified for the other tool post.

In the balance cut mode, balance cutting is performed when a move command in cutting feed is specified for both tool posts.

In balance cutting, the tool posts start moving simultaneously in each block in which a move command in cutting feed is specified.

Specify G68 or G69 in a single block.

NOTE

1 Balance cutting is not performed in dry run or machine lock state. G68 or G69 specified for one tool post is synchronized with G68 or G69 specified for the other tool post, however.

2 In the balance cut mode, G68 specified for one tool post is not synchronized with G68 specified for the other tool post. In the balance cut cancel mode, G69 specified for one tool post is not synchronized with G69 specified for the other tool post.

3 Balance cutting is not performed in a block in which 0 is specified for the travel distance.

4 Balance cutting is not performed when rapid traverse is specified.
Caution

⚠️ CAUTION
1. Balance cut only starts cutting feed on both tool posts at the same time; it does not maintain synchronization thereafter. To synchronize all the movements of both tool posts, the setting for both tool posts, such as the travel distance and feedrate, must be the same. Override and interlock can be applied independently to both tool posts. The settings for both tool posts that are related to override and interlock must also be the same to perform balance cutting.
2. After feed hold is applied during execution of balance cutting for both tool posts, balance cutting is not performed at the restart. Balance cutting is performed when the next move command is executed for both tool posts.

NOTE
1. Time delay before the pulse distribution of both tool posts is started is 2 msec or shorter.
2. Overlap is invalid. In the balance cut mode, synchronization is established at the start of each move block in which cutting is specified, so movement can momentarily stop.
3. In the balance cut mode, continuous thread cutting overlap is also invalid. Perform continuous thread cutting in the balance cut cancel mode.
4. To establish synchronization of the pulse distribution in a block in which thread cutting is specified, the same position coder must be selected.
5. The cancel mode (G69) is unconditionally set by a reset.
6. When the option "mirror image for double turret" is selected, the balance cut function cannot be used. To use the option “mirror image for double turret”, set bit 0 (NVC) of parameter No. 8137 to 0 to disable the balance cut function.
III. OPERATION
1 DATA INPUT/OUTPUT

By using the memory card interface on the left side of the display, information written in a memory card is read into the CNC and information is written from the CNC to a memory card. The following types of data can be input and output:

1. Y-axis offset data

The above data can be input and output on the screens used for displaying and setting the data and on the ALL IO screen.

Chapter 1, "DATA INPUT/OUTPUT", consists of the following sections:

1.1 INPUT/OUTPUT ON EACH SCREEN ...................................364
1.1.1 Inputting and Outputting Y-axis Offset Data ...............364
1.1.1.1 Inputting Y-axis offset data.............................364
1.1.1.2 Outputting Y-axis Offset Data.........................365
1.2 INPUT/OUTPUT ON THE ALL IO SCREEN .....................366
1.2.1 Inputting and Outputting Y-axis Offset Data.............367
1.1 INPUT/OUTPUT ON EACH SCREEN

Data can be input to and output from the Y-axis offset screens.

1.1.1 Inputting and Outputting Y-axis Offset Data

1.1.1.1 Inputting Y-axis offset data

Y-axis offset data is loaded into the memory of the CNC from a memory card. The input format is the same as the output format. The Y-axis offset data that is registered in the memory and has a corresponding data number is replaced with data input by this operation.

**Inputting Y-axis offset data (for 8.4/10.4-inch display unit)**

**Procedure**

1. Make sure the input device is ready for reading.
2. Press the EDIT switch on the machine operator’s panel.
3. Press function key \[Y\]
4. Press the continuous menu key \[\] several times until soft key \[Y OFFSET\] appears.
5. Press soft key \[Y OFFSET\] to display the Y-axis offset data screen.
6. Press soft key [(OPRT)].
7. Press the continuous menu key \[\] several times until soft key \[F INPUT\] appears.
8. Press soft key \[F INPUT\].
9. Type the name of the file that you want to input. If the input file name is omitted, default input file name "TOOLOFST.TXT" is assumed.
10. Press soft key \[EXEC\]. This starts reading the Y-axis offset data, and "INPUT" blinks in the lower right part of the screen. When the read operation ends, the "INPUT" indication disappears. To cancel the input, press soft key \[CANCEL\].
1.1.1.2 Outputting Y-axis Offset Data

Y-axis offset data is output in a output format from the memory of the CNC to a memory card.

Outputting Y-axis offset data (for 8.4/10.4-inch display unit)

Procedure

1. Make sure the output device is ready for outputting.
2. Press the EDIT switch on the machine operator’s panel.
3. Press function key .
4. Press the continuous menu key several times until soft key [Y OFFSET] appears.
5. Press soft key [Y OFFSET] to display the Y-axis offset data screen.
6. Press soft key [(OPRT)].
7. Press the continuous menu key several times until soft key [F OUTPUT] appears.
8. Press soft key [F OUTPUT].
9. Type the file name that you want to output.
   If the file name is omitted, default file name "TOOLOFST.TXT" is assumed.
10. Press soft key [EXEC].
    This starts outputting the Y-axis offset data, and “OUTPUT” blinks in the lower right part of the screen. When the read operation ends, the “OUTPUT” indication disappears.
    To cancel the output, press soft key [CANCEL].
1.2 INPUT/OUTPUT ON THE ALL IO SCREEN

Just by using the ALL IO screen, you can input and output Y-axis offset data and tool offset / 2nd geometry data.

The following explains how to display the ALL IO screen:

Displaying the ALL IO screen (for 8.4/10.4-inch display unit)

Procedure

1. Press function key  

2. Press the continuous menu key  several times until soft key [ALL IO] is displayed.

3. Press soft key [ALL IO] to display the ALL IO screen.

The subsequent steps to select data from the ALL IO screen will be explained for each type of data.
1.2.1 **Inputting and Outputting Y-axis Offset Data**

With the lathe system, Y-axis offset data can be input and output using the ALL IO screen.

**Inputting Y-axis offset data (for 8.4/10.4-inch display unit)**

**Procedure**

1. On the ALL IO screen, press the continuous menu key several times until soft key [Y OFFSET] is displayed.
2. Press soft key [Y OFFSET].
3. Select EDIT mode.
4. Press soft key [(OPRT)].
5. Press soft key [N INPUT].
6. Set the name of the file that you want to input. Type a file name, and press soft key [F NAME]. If the input file name is omitted, default file name "TOOLOFST.TXT" is assumed.
7. Press soft key [EXEC].
   This starts reading the Y-axis offset data, and "INPUT" blinks in the lower right part of the screen. When the read operation ends, the "INPUT" indication disappears.
   To cancel the input, press soft key [CANCEL].

**Outputting Y-axis offset data (for 8.4/10.4-inch display unit)**

**Procedure**

1. On the ALL IO screen, press the continuous menu key several times until soft key [Y OFFSET] is displayed.
2. Press soft key [Y OFFSET].
3. Select EDIT mode.
4. Press soft key [(OPRT)].
5. Press soft key [F OUTPUT].
6. Set the file name to be output.
   Type a file name, and press soft key [F NAME]. If the file name is omitted, default file name "TOOLOFST.TXT" is assumed.
7. Press soft key [EXEC].
   This starts outputting the Y-axis offset data, and "OUTPUT" blinks in the lower right part of the screen. When the read operation ends, the "OUTPUT" indication disappears.
   To cancel the output, press soft key [CANCEL].
Chapter 2, "SETTING AND DISPLAYING DATA", consists of the following sections:

2.1 SCREENS DISPLAYED BY FUNCTION KEY ..........369
  2.1.1 Setting and Displaying the Tool Offset Value ..........370
  2.1.2 Direct Input of Tool Offset Value .................................374
  2.1.3 Direct Input of Tool Offset Value Measured B ..........376
  2.1.4 Counter Input of Offset value .................................379
  2.1.5 Setting the Workpiece Coordinate System Shift Value 380
  2.1.6 Setting the Y-Axis Offset ........................................382
  2.1.7 Chuck and Tail Stock Barriers .................................385
2.1 SCREENS DISPLAYED BY FUNCTION KEY

Press function key to display or set tool compensation values and other data.
This section explains the display and setting of the following data items:
1. Tool offset value
2. Workpiece coordinate system shift value
3. Y-axis offset value
4. Chuck and tail stock barriers

For the display and setting of data other than the above, refer to “USER’S MANUAL (Common to Lathe System/Machining Center System)” (B-64304EN).
2.1.1 Setting and Displaying the Tool Offset Value

Dedicated screens are provided for displaying and setting tool offset values and tool nose radius compensation values. Whether to use tool geometry and wear compensation can be selected using bit 6 (NGW) of parameter No. 8136; whether to use tool nose radius compensation can be selected using bit 7 (NCR) of parameter No. 8136. (0: Use the function; 1: Does not use the function.)

**Setting and displaying the tool offset value and the tool nose radius compensation value**

**Procedure**

1. Press function key .
   When using a 2-path system, select, in advance, a path for which a tool offset value is to be set, by using the path selection switch.

2. Press chapter selection soft key [OFFSET] or press function key several times until the tool compensation screen is displayed.
   Different screens are displayed depending on whether tool geometry offset, wear offset, or neither is applied.

![Fig. 2.1.1 (a) When tool geometry/wear offset is not used (10.4-inch)](image)
3 Move the cursor to the compensation value to be set or changed using page keys and cursor keys, or enter the compensation number for the compensation value to be set or changed and press soft key [NO.SRH].

4 To set a compensation value, enter a value and press soft key [INPUT]. To change the compensation value, enter a value to add to the current value (a negative value to reduce the current value) and press soft key [+INPUT].

T (TIP) is the number of the imaginary tool nose.

T may be specified on the geometry compensation screen or on the wear compensation screen.
When tool nose radius compensation is not used (bit 7 (NCR) of parameter No. 8136 is set to 1), neither radius nor T (TIP) is displayed.

**Explanation**

- **Decimal point input**

A decimal point can be used when entering a compensation value.

- **Other method**

An external input/output device can be used to input or output a cutter compensation value. See Chapter III-8 “Data Input/Output” in the User’s Manual (Common to Lathe System/Machining Center System). Tool length compensation values can be set using the following functions described in subsequent subsections: direct input of tool offset value measured, direct input of tool offset value measured B, and counter input of offset value.

- **Number of tool compensation values**

Up to 64 (1-path system) or 200 (2-path system) tool compensation value sets are available.

When the function for 64 (1-path system) or 200 (2-path system) tool compensation value sets is not used (bit 5 (NDO) of parameter No. 8136 to 1), up to 32 tool compensation value sets are available.

For each set, tool geometry offset can be distinguished from the tool wear offset. (When bit 6 (NGW) of parameter No. 8136 is set to 0)

- **Disabling entry of compensation values**

In some cases, tool wear compensation or tool geometry compensation values cannot be input because of the settings in bits 0 (WOF) and 1 (GOF) of parameter No.3290. The number of the first tool offset amount of which entry is to be disabled can be set for parameter No. 3294 and the number of tool offset amounts following the start number can be set for parameter No. 3295 to disable entry of tool offset amounts within the specified range from the MDI.

Consecutive input values are set as follows:

1) When values are input for offset numbers, starting from one for which input is not inhibited to one for which input is inhibited, a warning is issued and values are set only for those offset numbers for which input is not inhibited.

2) When values are input for offset numbers, starting from one for which input is inhibited to one for which input is not inhibited, a warning is issued and no values are set.

- **Displaying radius and T (TIP)**

When tool nose radius compensation is not used according to the setting, neither radius nor T (TIP) is displayed. (Bit 7 (NCR) of parameter No. 8136 is set to 1.)
- Changing offset values during automatic operation

When offset values have been changed during automatic operation, bits 4 (LGT) and 6 (LWM) of parameter No.5002 can be used for specifying whether new offset values become valid in the next move command or in the next T code command.

<table>

Fig. 2.1.1 (a)
2.1.2 Direct Input of Tool Offset Value

To set the difference between the tool reference position used in programming (the nose of the standard tool, turret center, etc.) and the tool nose position of a tool actually used as an offset value.

Direct input of tool offset value

Procedure

- Setting of Z axis offset value

1. Cut surface A in manual mode with an actual tool. Suppose that a workpiece coordinate system has been set.

![Fig. 2.1.2 (a) Tool offset screen (10.4-inch)](image)

2. Release the tool in X-axis direction only, without moving Z-axis and stop the spindle.

3. Measure distance $\beta$ from the origin in the workpiece coordinate system to surface A. Set this value as the measured value along the Z-axis for the desired offset number, using the following procedure:

![Fig. 2.1.2 (b) Tool offset screen (10.4-inch)](image)
3-1 Press the function key or the soft key [OFFSET] to display the tool offset screen. If geometry compensation values and wear offset values are separately specified, display the screen for either of them.

3-2 Move the cursor to the set offset number using cursor keys.

3-3 Press the address key to be set.

3-4 Key in the measured value (β).

3-5 Press the soft key [MEASURE].

The difference between measured value β and the coordinate is set as the offset value.

- Setting of X axis offset value

4 Cut surface B in manual mode.

5 Release the tool in the Z-axis direction without moving the X-axis and stop the spindle.

6 Measure the diameter α of surface B.

Set this value as the measured value along the X-axis for the desired offset number in the same way as when setting the value along the Z-axis.

7 Repeat above procedure the same time as the number of the necessary tools.

The offset value is automatically calculated and set.

For example, in case α=69.0 when the coordinate value of surface B in the diagram above is 70.0, set 69.0 [MEASURE] at offset No. 2. In this case, 1.0 is set as the X-axis offset value to offset No. 2.

Explanation

- Offset values for a program created in diameter programming

Enter diameter values for the offset values for axes for which diameter programming is used.

- Tool geometry offset value and tool wear offset value

If measured values are set on the tool geometry offset screen, all offset values become geometry offset values and all wear offset values are set to 0. If measured values are set on the tool wear offset screen, the differences between the measured offset values and the current wear offset values become the new offset values.

- Release of both axes

When the record button is provided on the machine side, the tool can be released in the directions of the two axes by setting bit 2 (PRC) of parameter No. 5005 or using the position record signal. For details on the position record signal, refer to the manual issued by the machine tool builder.
2.1.3 Direct Input of Tool Offset Value Measured B

Explanation

- Basic procedure to set tool offset value

To use the tool setter function for a one–turret/two–spindle lathe, first specify the spindle to be measured, using the S2TLS (G040.5) (spindle measurement select) signal.

   By executing manual reference position return, a machine coordinate system is established.
   The tool offset value is computed on the machine coordinate system.

2. Select manual handle mode or manual continuous feed mode and set the tool compensation value write mode select signal GOQSM to “1”. The LCD display is automatically changed to the tool offset screen (geometry), and the “OFST” indicator starts blinking in the status indication area at the bottom of the screen, which indicates that the tool compensation value writing mode is ready. When the tool setter function for a one–turret/two–spindle lathe is in use, the S1MES or S2MES (spindle under measurement) signal, whichever is applicable, becomes 1.

⚠️ CAUTION
After this, it is impossible to switch the S2TLS (spindle measurement selection) signal until the GOQSM (offset write mode) signal becomes 0.

3. Select a tool to be measured.

4. When the cursor does not coincide with the tool offset number desired to be set, move the cursor to the desired offset number using the page key and cursor key.
   The cursor can also be coincided with the tool offset number desired to be set automatically by the tool offset number input signals (when parameter QNI(No.5005#5)=1).
   In this case, the position of the cursor cannot be changed on the tool compensation screen using page keys or cursor keys.

5. Near the tool to the sensor by manual operation.

6. Place the tool edge to a contacting surface of the sensor by manual handle feed.
   Bring the tool edge in contact with the sensor. This causes the tool compensation value writing signals to input to be CNC.
   The following tool compensation amount write signals are set up according to the setting of the bit 3 (TS1) of parameter No. 5004.
   When the parameter is 0: +MIT1, −MIT1, +MIT2, −MIT2
   When the parameter is 1: +MIT1 only
   If the tool compensation value writing signal is set to “1”:
   i) The axis is interlocked in this direction and its feed is stopped.
   ii) The tool offset value extracted by the tool offset memory (tool geometry offset value) which corresponds to the offset number shown by the cursor is set up.
(7) For both X-axis and Z-axis, their offset values are set by operations (5) and (6).
(8) Repeat operations (3) to (7) for all necessary tools.
(9) Set the tool compensation value writing mode signal GOQSM to “0”.
   The writing mode is canceled and the blinking “OFST” indicator light goes off.
   When the tool setter function for a one–turret/two–spindle lathe is in use, the S1MES or S2MES (spindle under measurement) signal for the spindle being measured becomes 0.

- Basic procedure to set workpiece coordinate shift value

To use the tool setter function for a one–turret/two–spindle lathe, first specify the spindle to be measured, using the S2TLS <G040.5> (spindle measurement select) signal.
(1) Set the tool geometry offset values of each tool in advance.
(2) Execute manual reference position return.
   By executing manual reference position return, the machine coordinate system is established.
   The workpiece coordinate system shift amount is computed based on the machine coordinate system of the tool.
(3) Set the workpiece coordinate system shift amount writing mode select signal WOQSM to “1”.
   The LCD display automatically switches to the workpiece shifting screen, the “WFST” indicator starts blinking at the status indicator area in the bottom of the screen, which indicates that the workpiece coordinate system shift amount writing mode is ready.
   When the tool setter function for a one–turret/two–spindle lathe is in use, the workpiece coordinate system screen is selected, and the S1MES or S2MES (spindle under measurement) signal, whichever is applicable, becomes 1.

⚠️ CAUTION
After this, it is impossible to switch the S2TLS (spindle measurement selection) signal until the WOQSM (offset write mode) signal becomes 0.

(4) Select a tool to be measured.
(5) Check tool offset numbers.
   The tool offset number corresponding to the tool required for measurement, shall be set in the parameter (No.5020) in advance.
   The tool offset number can also be set automatically by setting the tool offset number input signal (with parameter QNI(No.5005#5)=1).
(6) Manually approach the tool to an end face of the workpiece.
(7) Place the tool edge to the end face (sensor) of the workpiece using manual handle feed.
   When the tool edge contacts the end face of the workpiece, input the workpiece coordinate system shift amount signal WOSET.
   The workpiece coordinate system shift amount on the Z–axis is automatically set.
(8) Release the tool.
(9) Set the workpiece coordinate system shift amount write mode select signal WOQSM to “0”. The writing mode is canceled and the blinking “WSFT” indicator light goes off.
When the tool setter function for a one–turret/two–spindle lathe is in use, the S1MES or S2MES (spindle under measurement) signal, whichever is applicable, becomes 0.
2.1.4 Counter Input of Offset value

By moving the tool until it reaches the desired reference position, the corresponding tool offset value can be set.

Counter input of offset value

Procedure

1. Manually move the reference tool to the reference position.
2. Reset the relative coordinates along the axes to 0.
3. Move the tool for which offset values are to be set to the reference position.
4. Select the tool offset screen. Move the cursor to the offset value to be set using cursor keys.

5. Press address key X (or Z) and the soft key [INP.C.].

Explanation

- Geometry offset and wear offset
When the above operations are performed on the tool geometry offset screen, tool geometry offset values are input and tool wear offset values do not change.

When the above operations are performed on the tool wear offset screen, tool wear offset values are input and tool geometry offset values do not change.
2.1.5 Setting the Workpiece Coordinate System Shift Value

The set coordinate system can be shifted when the coordinate system which has been set by a G50 command (or G92 command for G code system B or C) or automatic coordinate system setting is different from the workpiece coordinate system assumed at programming. When a T series system is used, the workpiece coordinate system shift screen is displayed.

### Setting the workpiece coordinate system shifting amount

**Procedure**

1. Press function key .
2. Press the continuous menu key several times until the screen with soft key [W.SHFT] is displayed.
3. Press soft key [W.SHFT].
4. Move the cursor using cursor keys to the axis along which the coordinate system is to be shifted.
5. Enter the shift value and press soft key [INPUT].

![Fig. 2.1.5 (a) Workpiece coordinate system shift screen (10.4-inch)](image)

- Move the cursor using cursor keys to the axis along which the coordinate system is to be shifted.
- Enter the shift value and press soft key [INPUT].

![Fig. 2.1.5 (b)](image)
Explanation

- When shift values become valid
  Shift values become valid immediately after they are set.

- Shift values and coordinate system setting command
  Setting a command (G50 or G92) for setting a coordinate system disables the set shift values.
  Example)
  When G50 X100.0 Z80.0; is specified, the coordinate system is set so that the current tool reference position is X+100.0, Z+80.0 regardless of the shift values.

- Shift values and coordinate system setting
  If the automatic coordinate system setting is performed by manual reference position return after shift amount setting, the coordinate system is shifted instantly.

- Diameter or radius value
  Whether the shift amount on the X-axis is diameter or radius value depends on that specified in program.

- Position record signal
  When bit 2 (PRC) of parameter No. 5005 is 1, the absolute coordinates when the position record signal is ON are recorded for calculation of the shift amount.

Example

When the actual position of the reference point is X=121.0 (diameter), Z=69.0 with respect to the workpiece origin but it should be X=120.0, Z=70.0, set the following shift values:
Shift value setting: X=1.0, Z=-1.0

Fig. 2.1.5 (c)
2.1.6 Setting the Y-Axis Offset

Tool position offset values along the Y-axis can be set. Counter input of offset values is also possible.

For the Y-axis, no tool offset value can be directly input.

Whether the Y-axis offset is to be used can be selected using bit 1 (YOF) of parameter No. 8132. (0: Does not use the Y-axis offset./1: Uses the Y-axis offset.)

When the Y-axis is not used according to the setting, the screen is not also displayed.

Procedure for setting the tool offset value of the Y axis

Procedure

1. Press function key 

2. Press the continuous menu key several times until the screen with soft key [Y OFFSET] is displayed.

3. Press soft key [Y OFFSET]. The Y-axis offset screen is displayed.

Fig. 2.1.6 (a) Y-axis offset screen (10.4-inch)
3-1 When the [GEOMETRY] soft key is pressed, Y-axis tool geometry compensation data is displayed. Press the [WEAR] soft key to switch the screen display to the display of tool wear compensation data.

4 Position the cursor at the offset number to be changed by using either of the following methods:
   - Move the cursor to the offset number to be changed using page keys and cursor keys.
   - Type the offset number and press soft key [NO.SRH].

5 Enter the offset value.

6 Press soft key [INPUT]. The offset value is set and displayed.
Procedure for counter input of the offset value

Procedure

To set relative coordinates along the Y-axis as offset values:

1. Move the reference tool to the reference point.
2. Reset relative coordinate Y to 0.
3. Move the tool for which offset values are to be set to the reference point.
4. Move the cursor to the value for the offset number to be set, press \( \text{key}, \) then press soft key [INP.C.].

Relative coordinate Y (or V) is now set as the offset value.
2.1.7 Chuck and Tail Stock Barriers

The chuck and tail stock barrier function prevents damage to the machine by checking whether the tool nose fouls either the chuck or tail stock. Specify an area into which the tool may not enter (entry-inhibition area). This is done using the special setting screen, according to the shapes of the chuck and tail stock. If the tool nose should enter the set area during a machining operation, this function stops the tool and outputs an alarm message. The tool can be cleared from the area only by retracting it in the direction opposite to that in which the tool entered the area.

Whether the chuck and tail stock barrier function is to be used can be selected using bit 1 (BAR) of parameter No. 8134. (0: Does not use the function; 1: Uses the function.) When the function is not used, the screen is not also displayed.

Setting the chuck and tail stock barriers

Procedure

- Setting the shapes of the chuck and tail stock

1. Press function key [F].
2. Press the continuous menu key [C]. Then, press chapter selection soft key [BARRIER].
3. Pressing the page key [PAGE] or [PREV] toggles the display between the chuck barrier setting screen and tail stock barrier setting screen.

---

Fig. 2.1.7 (a) Chuck barrier setting screen (10.4-inch)
4. Position the cursor to each item defining the shape of the chuck or tail stock, enter the corresponding value, then press soft key [INPUT]. The value is set. Pressing soft key [+INPUT] after a value has been entered adds the entered value to the current value, the new setting being the sum of the two values.

Items CX and CZ, both on the chuck barrier setting screen, and item TZ on the tail stock barrier setting screen can also be set in another way. Manually move the tool to the desired position, then press soft key [SETTING] to set the coordinate(s) of the tool in the workpiece coordinate system. If a tool having an offset other than 0 is manually moved to the desired position with no compensation applied, compensate for the tool offset in the set coordinate system. Items other than CX, CZ, and TZ cannot be set by using soft key [SETTING].

Example

When an alarm is issued, the tool stops before the entry-inhibition area if bit 7 (BFA) of parameter No. 1300 is set to 1. If bit 7 (BFA) of parameter No. 1300 is set to 0, the tool stops at a more inside position than the specified figure because the CNC and machine system stop with some delay in time.

For safety, therefore, set an area a little larger than the determined area. The distance between the boundaries of these two areas, L, is calculated from the following equation, based on the rapid traverse rate.

\[ L = \frac{1}{7500} \times \text{Rapid traverse rate} \]

When the rapid traverse rate is 15 m/min, for example, set an area having a boundary 2 mm outside that of the determined area.

The shapes of the chuck and tail stock can be set using parameters Nos. 1330 to 1348.
NOTE
Set G23 mode before attempting to specify the shapes of the chuck and tail stock.

- Reference position return
Return the tool to the reference position along the X- and Z-axes. The chuck-tail stock barrier function becomes effective only once reference position return has been completed after power on. When an absolute position detector is provided, reference position return need not always be performed. The positional relationship between the machine and the absolute position detector, however, must be determined.

- G22/G23
When G22 (stored stroke limit on) is specified, the chuck and tail stock area becomes an entry-inhibition area. When G23 (stored stroke limit off) is specified, the entry-inhibition area is canceled. Even if G22 is specified, the entry-inhibition area for the tail stock can be disabled by issuing a tail stock barrier signal. When the tail stock is pushed up against a workpiece or separated from the workpiece by using the auxiliary functions, PMC signals are used to enable or disable the tail stock setting area.

<table>

<td>Invalid</td>
</tr>
</tbody>
</table>

G22 is selected when the power is turned on. Using G23, bit 7 of parameter No. 3402, however, it can be changed to G23.
2. SETTING AND DISPLAYING DATA

OPERATION

Explanation
- Setting the shape of the chuck barrier

![Diagram showing two scenarios for setting the shape of the chuck barrier: one for holding the outer face of a tool and another for holding the inner face of a tool. Diagram includes labels for X, Y, Z, CX, CZ, L, W, W1, L1, and A.]

Note) The hatched areas indicate entry-inhibition areas.

</tbody>
</table>

TY : Selects a chuck type, based on its shape. Specifying 0 selects a chuck that holds the inner face of a tool. Specifying 1 selects a chuck that holds the outer face of a tool. A chuck is assumed to be symmetrical about its Z-axis.

CX, CZ :
Specify the coordinates of a chuck position, point A, in the workpiece coordinate system. These coordinates are not the same as those in the machine coordinate system. The unit of data is indicated in Table 2.1.7(c).

† CAUTION
Whether diameter programming or radius programming is used for the axis determines the programming system. When diameter programming is used for the axis, use diameter programming to enter data for the axis.
Table 2.1.7 (c)

</tr>
</tbody>
</table>

L, L1, W, W1 : Define the figure of a chuck. The unit of data is indicated in Table 2.1.7(c).

\[\text{CAUTION}\]

Always specify W and W1 in radius. When radius programming is used for the Z-axis, specify L and L1 in radius.

- Setting the shape of a tail stock barrier

TZ : Specifies the Z coordinate of the chuck position, point B, in the workpiece coordinate system. These coordinates are not the same as those in the machine coordinate system. The unit of data is indicated in Table 2.1.7(c). A tail stock is assumed to be symmetrical about its Z-axis.
CAUTION
Whether diameter programming or radius programming is used for the Z-axis determines the programming system.

L, L1, L2, D, D1, D2, D3 :
Define the figure of a tail stock. The valid data range is indicated in Table 2.1.7(c).

CAUTION
Always specify D, D1, D2, and D3 in diameter programming. When radius programming is used for the Z-axis, specify L, L1, and L2 in radius.

- Setting the entry-inhibition area for the tail stock tip
The tip angle of the tail stock is 60 degrees. The entry-inhibition area is set around the tip, assuming the angle to be 90 degrees, as shown below.

Limitation
- Correct setting of an entry-inhibition area
If an entry-inhibition area is incorrectly set, it may not be possible to make the area effective. Avoid making the following settings:
- L ≤ L1 or W ≤ W1 in the chuck-shape settings.
- D2 ≤ D3 in the tail stock-shape settings.
- A chuck setting overlapping that of the tail stock.

- Retraction from the entry-inhibition area
If the tool enters the entry-inhibition area and an alarm is issued, switch to manual mode, retract the tool manually, then reset the system to release the alarm. In manual mode, the tool can be moved only in the opposite direction to that in which the tool entered the area.
The tool cannot be moved in the same direction (further into the area) as it was traveling when the tool entered the area.
When the entry-inhibition areas for the chuck and tail stock are enabled, and the tool is already positioned within those areas, an alarm is issued when the tool moves.
When the tool cannot be retracted, change the setting of the entry-inhibition areas, such that the tool is outside the areas, reset the system to release the alarm, then retract the tool. Finally, reinstall the original settings.
- Coordinate system

An entry-inhibition area is defined using the workpiece coordinate system. Note the following.

<1> When the workpiece coordinate system is shifted by means of a command or operation, the entry-inhibition area is also shifted by the same amount.

![Diagram of Coordinate System](image)

Fig. 2.1.7 (e)

Use of the following commands and operations will shift the workpiece coordinate system.

Commands:
- G54 to G59, G52, G50 (G92 in G code system B or C)

Operations:
- Manual handle interruption, change in offset relative to the workpiece origin, change in tool offset (tool geometry offset), operation with machine lock, manual operation with machine absolute signal off

<2> When the tool enters an entry-inhibition area during automatic operation, set the manual absolute signal, *ABSM, to 0 (on), then manually retract the tool from the area. If this signal is 1, the distance the tool moves in manual operation is not counted in the tool coordinates in the workpiece coordinate system. This results in the state where the tool can never be retracted from the entry-inhibition area.

- Stored stroke check 2/3

When both stored stroke check 2/3 and the chuck tail stock barrier function are provided, the barrier takes priority over the stored stroke check. Stored stroke check 2/3 is ignored.
APPENDIX
This manual describes all parameters indicated in this manual. For those parameters that are not indicated in this manual and other parameters, refer to the parameter manual.

Appendix A, "PARAMETERS", consists of the following sections:

A.1 DESCRIPTION OF PARAMETERS ........................................396
A.2 DATA TYPE............................................................................447
A.3 STANDARD PARAMETER SETTING TABLES ..................448
A.1 DESCRIPTION OF PARAMETERS

### #0 FCV
- **[Input type]**: Setting input
- **[Data type]**: Bit path

0: Series 0 standard format
   (This format is compliant with the Series 0i-C.)
1: Series 10/11 format

**NOTE**
1. Programs created in the Series 10/11 program format can be used for operation on the following functions:
   1. Subprogram call M98, M198
   2. Thread cutting with equal leads G32 (T series)
   3. Canned cycle G90, G92, G94 (T series)
   4. Multiple repetitive canned cycle G71 to G76 (T series)
   5. Drilling canned cycle G80 to G89 (T series)
2. When the program format used in the Series 10/11 is used for this CNC, some limits may add. Refer to the User’s Manual.

### #1 IESPx
- **[Input type]**: Parameter input
- **[Data type]**: Bit axis

**NOTE**
When at least one of these parameters is set, the power must be turned off before operation is continued.

### ISA
Increment system of each axis

<table>
<thead>
<tr>
<th>Increment system</th>
<th>#0 ISAx</th>
<th>#1 ISCx</th>

<td>0</td>
</tr>
<tr>
<td>IS-C</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
# 7  IESP  When the least input increment is C (IS-C), the function to allow to set
the larger value to the parameter of the speed and the acceleration:
0:  Not used.
1:  Used.

As for the axis which set this parameter when the least input
increment is C (IS-C), the larger value can be set to the parameter of
the speed and the acceleration.
The valid data ranges of these parameters are indicated in the table of
velocity and angular velocity parameters in (C) of the standard
parameter setting tables and the table of acceleration and angular
acceleration parameters in (D).
When this function is made effective, the digit number below the
decimal point of the parameter on input screen is changed. The digit
number below the decimal point decreases by one digit in case of the
least input increment C (IS-C).

</tbody>
</table>

In general, the increment system and diameter/radius specification of
an axis set as a parallel axis are to be set in the same way as for the
basic three axes.
Reference axis

[Input type] Parameter input  
[Data type] Byte path  
[Valid data range] 1 to Number of controlled axes

The unit of some parameters common to all axes such as those for dry run feedrate and one-digit F code feed may vary according to the increment system. An increment system can be selected by a parameter on an axis-by-axis basis. So, the unit of those parameters is to match the increment system of a reference axis. Set which axis to use as a reference axis.

Among the basic three axes, the axis with the finest increment system is generally selected as a reference axis.

Distance between two opposite tool posts in mirror image

[Input type] Parameter input  
[Data type] Real path  
[Unit of data] mm, inch (input unit)  
[Minimum unit of data] Depend on the increment system of the reference axis  
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))  
(When the increment system is IS-B, 0.0 to +999999.999)

Set the distance between two opposite tool posts in mirror image.

Profile of a chuck

[Input type] Parameter input  
[Data type] Byte path  
[Valid data range] 0 to 1

Select a chuck figure.

0: Chuck which holds a workpiece on the inner surface
1: Chuck which holds a workpiece on the outer surface
1331 Dimensions of the claw of a chuck (L)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L) of the claw of the chuck.

NOTE
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1332 Dimensions of the claw of a chuck (W)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the width (W) of the claw of the chuck.

NOTE
Specify this parameter by using a radius value at all times.

1333 Dimensions of the claw of a chuck (L1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L1) of the claw of the chuck.

NOTE
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
1334  Dimensions of the claw of a chuck (W1)

- Input type: Parameter input
- Data type: Real path
- Unit of data: mm, inch (input unit)
- Minimum unit of data: Depend on the increment system of the applied axis
- Valid data range: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
  (When the increment system is IS-B, 0.0 to +999999.999)

Set the width (W1) of the claw of the chuck.

**NOTE**
Specify this parameter by using a radius value at all times.

1335  X coordinate of a chuck (CX)

- Input type: Parameter input
- Data type: Real path
- Unit of data: mm, inch (input unit)
- Minimum unit of data: Depend on the increment system of the applied axis
- Valid data range: 9 digit of minimum unit of data (refer to standard parameter setting table (A))
  (When the increment system is IS-B, -999999.999 to +999999.999)

Set the chuck position (X coordinate) in the workpiece coordinate system.

**NOTE**
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
1336  Z coordinate of a chuck (CZ)

[Input type] Parameter input  
[Data type] Real path  
[Unit of data] mm, inch (input unit)  
[Minimum unit of data] Depend on the increment system of the applied axis  
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))  
(When the increment system is IS-B, -999999.999 to +999999.999)  
Set the chuck position (Z coordinate) in the workpiece coordinate system.

NOTE  
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1341  Length of a tail stock (L)

[Input type] Parameter input  
[Data type] Real path  
[Unit of data] mm, inch (input unit)  
[Minimum unit of data] Depend on the increment system of the applied axis  
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))  
(When the increment system is IS-B, 0.0 to +999999.999)  
Set the length (L) of the tail stock.

NOTE  
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1342  Diameter of a tail stock (D)

[Input type] Parameter input  
[Data type] Real path  
[Unit of data] mm, inch (input unit)  
[Minimum unit of data] Depend on the increment system of the applied axis  
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))  
(When the increment system is IS-B, 0.0 to +999999.999)  
Set the diameter (D) of the tail stock.

NOTE  
Specify this parameter by using a diameter value at all times.
1343  Length of a tail stock (L1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L1) of the tail stock.

NOTE
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.

1344  Diameter of a tail stock (D1)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the diameter (D1) of the tail stock.

NOTE
Specify this parameter by using a diameter value at all times.

1345  Length of a tail stock (L2)

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the applied axis
[Valid data range] 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
(When the increment system is IS-B, 0.0 to +999999.999)
Set the length (L2) of the tail stock.

NOTE
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
### 1346 Diameter of a tail stock (D2)

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))

Set the diameter (D2) of the tail stock.

**NOTE**
Specify this parameter by using a diameter value at all times.

### 1347 Diameter of the hole of a tail stock (D3)

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))

Set the diameter (D3) of the tail stock.

**NOTE**
Specify this parameter by using a diameter value at all times.

### 1348 Z coordinate of a tail stock (TZ)

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: 9 digit of minimum unit of data (refer to standard parameter setting table (A))

Set the tail stock position (Z coordinate) in the workpiece coordinate system.

**NOTE**
Whether to specify this parameter by using a diameter value or radius value depends on whether the corresponding axis is based on diameter specification or radius specification.
# A. PARAMETERS

## APPENDIX

**# 1 LRP**
Positioning (G00)
- **0**: Positioning is performed with non-linear type positioning so that the tool moves along each axis independently at rapid traverse.
- **1**: Positioning is performed with linear interpolation so that the tool moves in a straight line.

**# 4 RF0**
When cutting feedrate override is 0% during rapid traverse,
- **0**: The machine tool does not stop moving.
- **1**: The machine tool stops moving.

**# 4 ROC**
In the threading cycles G92 and G76, rapid traverse override for retraction after threading is finished is:
- **0**: Effective
- **1**: Not effective (Override of 100%)

## Rapid Traverse Rate for Each Axis

- **Input type**: Parameter input
- **Data type**: Real axis
- **Unit of data**: mm/min, inch/min, degree/min (machine unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: Refer to the standard parameter setting table (C)

- **Example**: (When the increment system is IS-B, 0.0 to +999000.0)

Specify the maximum cutting feedrate for each axis.
1466  Feedrate for retraction in threading cycle G92, G76 or G76.7

[Input type] Parameter input  
[Data type] Real path  
[Unit of data] mm/min, inch/min (machine unit)  
[Minimum unit of data] Depend on the increment system of the reference axis  
[Valid data range] Refer to the standard parameter setting table (C)  

(When the increment system is IS-B, 0.0 to +999000.0)
When threading cycle G92, G76 or G76.7 is specified, retraction is performed after threading. Set a feedrate for this retraction.

NOTE
When this parameter is set to 0 or bit 1 (CFR) of parameter No. 1611 is set to 1, the rapid traverse rate set in parameter No. 1420 is used.

### 1610

<table>
<thead>
<tr>
<th>#7</th>
<th>#6</th>
<th>#5</th>
<th>#4</th>
<th>#3</th>
<th>#2</th>
<th>#1</th>
<th>#0</th>
</tr>
</thead>
<tbody>
<tr>
<td>THLx</td>
<td>JGLx</td>
<td>CTLx</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[Input type] Parameter input  
[Data type] Bit axis

# 0  **CTLx**  Acceleration/deceleration in cutting feed or dry run  
0: Exponential acceleration/deceleration is applied.  
1: Linear acceleration/deceleration after interpolation is applied.

# 4  **JGLx**  Acceleration/deceleration in jog feed  
0: Exponential acceleration/deceleration is applied.  
1: The same acceleration/deceleration as for cutting feedrate is applied.  
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)

# 5  **THLx**  Acceleration/deceleration in threading cycles  
0: Exponential acceleration/deceleration is applied.  
1: The same acceleration/deceleration as for cutting feedrate is applied.  
(Depending on the settings of bits 1 (CTBx) and 0 (CTLx) of parameter No. 1610)
As the time constant and FL feedrate, however, the settings of parameter Nos. 1626 and 1627 for threading cycles are used.
For retraction after threading in the threading cycles G92, G76 and G76.7:

0: The type of acceleration/deceleration after interpolation for threading is used together with the threading time constant (parameter No. 1626) and FL feedrate (parameter No. 1627).

1: The type of acceleration/deceleration after interpolation for rapid traverse is used together with the rapid traverse time constant.

NOTE
If this parameter is set to 1, a check is made before a retraction to see that the specified feedrate has become 0 (the delay in acceleration/deceleration has become 0). For retraction, the rapid traverse rate (parameter No. 1420) is used, regardless of the setting of parameter No. 1466. When this parameter is set to 0, parameter No. 1466 is used as the feedrate for retraction. As acceleration/deceleration used for retraction, only acceleration/deceleration after interpolation is used. Rapid traverse before look-ahead interpolation is disabled.

Set a time constant for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis.
1627  FL rate for acceleration/deceleration in threading cycles for each axis

[Input type] Parameter input  
[Data type] Real axis  
[Unit of data] mm/min, inch/min, degree/min (machine unit)  
[Minimum unit of data] Depend on the increment system of the applied axis  
[Valid data range] Refer to the standard parameter setting table (C)  
(When the increment system is IS-B, 0.0 to +999000.0)  
Set an FL feedrate for acceleration/deceleration after interpolation in the threading cycles G92 and G76 for each axis. Set 0 at all times except in a special case.

3032  Allowable number of digits for the T code

[Input type] Parameter input  
[Data type] Byte path  
[Valid data range] 1 to 8  
Set the allowable numbers of digits for the M, S, and T codes. When 0 is set, the allowable number of digits is assumed to be 8.

3290  

[Input type] Parameter input  
[Data type] Bit path  

# 0  WOF Setting the tool offset value (tool wear offset) by MDI key input is:  
0:  Not disabled.  
1:  Disabled. (With parameter No.3294 and No.3295, set the offset number range in which updating the setting is to be disabled.)

NOTE  
The tool offset set in the parameter WOF is followed even if geometric compensation and wear compensation are not specified.

# 1  GOF Setting the tool geometry offset value by MDI key input is:  
0:  Not disabled.  
1:  Disabled. (With parameter No.3294 and No.3295, set the offset number range in which updating the setting is to be disabled.)
3294  Start number of tool offset values whose input by MDI is disabled

3295  Number of tool offset values (from the start number) whose input by MDI is disabled

[Input type]  Parameter input
[Data type]  Word path
[Valid data range]  0 to Tool compensation count - 1

When the modification of tool offset values by MDI key input is to be disabled using bit 0 (WOF) of parameter No.3290 and bit 1 (GOF) of parameter No.3290, parameter Nos.3294 and 3295 are used to set the range where such modification is disabled. In parameter No.3294, set the offset number of the start of tool offset values whose modification is disabled. In parameter No.3295, set the number of such values. In the following cases, however, none of the tool offset values may be modified:

- When 0 or a negative value is set in parameter No.3294
- When 0 or a negative value is set in parameter No.3295
- When a value greater than the maximum tool offset number is set in parameter No.3294

In the following case, a modification to the values ranging from the value set in parameter No.3294 to the maximum tool offset number is disabled:
- When the value of parameter No.3294 added to the value of parameter No.3295 exceeds the maximum tool offset number

When the offset value of a prohibited number is input through the MDI panel, the warning "WRITE PROTECT" is issued.

[Example]
When the following parameter settings are made, modifications to both of the tool geometry offset values and tool wear offset values corresponding to offset numbers 51 to 60 are disabled:

- Bit 1 (GOF) of parameter No.3290 = 1 (to disable tool geometry offset value modification)
- Bit 0 (WOF) of parameter No.3290 = 1 (to disable tool wear offset value modification)
- Parameter No.3294 = 51
- Parameter No.3295 = 10

If the setting of bit 0 (WOF) of parameter No.3290 is set to 0 without modifying the other parameter settings above, tool geometry offset value modification only is disabled, and tool wear offset value modification is enabled.

#7  #6  #5  #4  #3  #2  #1  #0
3405

[Input type] Parameter input
[Data type] Bit path

# 4  CCR Addresses used for chamfering
0: Address is “I”, “J”, or “K”.
   In direct drawing dimension programming, addresses ",C", ",R", and ",A" (with comma) are used in stead of "C", "R", and "A".
1: Address is “C”.
   Addresses used for direct drawing dimension programming are "C", "R", and "A" without comma.

NOTE
If this bit (CCR) is set to 0, the function for changing the compensation direction by specifying I, J, or K in a G01 block in the tool nose radius compensation mode cannot be used.
If this bit (CCR) is set to 1 when address C is used as an axis name, the chamfer function cannot be used.

# 5  DDP Angle commands by direct drawing dimension programming
0: Normal specification
1: A supplementary angle is given.

#0  CRD If the functions of chamfering or corner R and direct drawing dimension programming are both enabled,
0: Chamfering or corner R is enabled.
1: Direct drawing dimension programming is enabled.
Specify which function is used when both the chamfering/corner R function and the drawing dimension programming function are enabled.
# 1  LGN  Geometry offset number of tool offset
0:  Is the same as wear offset number
1:  Specifies the geometry offset number by the tool selection number

**NOTE**
This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

# 2  LWT  Tool wear compensation is performed by:
0:  Moving the tool.
1:  Shifting the coordinate system.

**NOTE**
This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

# 4  LGT  Tool geometry compensation
0:  Compensated by the shift of the coordinate system
1:  Compensated by the tool movement

**NOTE**
This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

# 5  LGC  When tool geometry compensation is based on coordinate shifting, the tool geometry offset is:
0:  Not canceled by a command with offset number 0.
1:  Canceled by a command with offset number 0.

**NOTE**
This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

# 6  LWM  Tool offset operation based on tool movement is performed:
0:  In a block where a T code is specified.
1:  Together with a command for movement along an axis.
# 7  WNP  Imaginary tool tip number used for tool nose radius compensation, when the geometry/wear compensation function is equipped (bit 6 (NGW) of parameter No. 8136 is 0), is the number specified by:

0: Geometry offset number
1: Wear offset number

<table>
<thead>
<tr>

<td>Type A</td>
<td>A compensation vector perpendicular to the block next to the startup block or the block preceding the cancellation block is output.</td>
</tr>
</tbody>
</table>

![Diagram](G41, N1, N2, Intersection point, Tool nose radius center path, Tool center path, Programmed path)

| 0   | 1   | Type B | A compensation vector perpendicular to the startup block or cancellation block and an intersection vector are output. |

![Diagram](G41, N1, N2, Intersection point, Tool nose radius center path, Tool center path, Programmed path)

| 1   | 0   | Type C | When the startup block or cancellation block specifies no movement operation, the tool is shifted by the cutter compensation amount in a direction perpendicular to the block next to the startup or the block before cancellation block. |

![Diagram](G41, N1, N2, Intersection point, Shift, Tool nose radius center path, Tool center path, Programmed path)

When the block specifies movement operation, the type is set according to the SUP setting; if SUP is 0, type A is set, and if SUP is 1, type B is set.

**NOTE**

When SUV,SUP = 0,1 (type B), an operation equivalent to that of FS0_i-TC is performed.
#7  TGC  A tool geometry offset based on a coordinate shift is:
0:  Not canceled by reset.
1:  Canceled by reset.

**NOTE**
This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

**Input type**  Parameter input
**Data type**  Bit path

#1  ORC  The setting of a tool offset value is corrected as:
0:  Diameter value
1:  Radius value

**NOTE**
This parameter is valid only for an axis based on diameter specification. For an axis based on radius specification, specify a radius value, regardless of the setting of this parameter.

#3  TS1  For touch sensor contact detection with the function for direct input of offset value measured B (T series):
0:  Four-contact input is used.
1:  One-contact input is used.

<table>

</tbody>
</table>

**Input type**  Parameter input
**Data type**  Bit path

#2  PRC  For direct input of a tool offset value or workpiece coordinate system shift amount:
0:  The PRC signal is not used.
1:  The PRC signal is used.

#5  QNI  With the function for direct input of offset value measured B, a tool compensation number is selected by:
0:  Operation through the MDI panel by the operator (selection based on cursor operation).
1:  Signal input from the PMC.
A tool offset (geometry/wear) based on a tool movement and wear offset based on a coordinate shift are:
0: Not canceled by reset.
1: Canceled by reset.

These bits are used to select an interference check method in the cutter compensation or tool nose radius compensation mode.

<table>
<thead>
<tr>

<td>1</td>
<td>Interference check is enabled. Only the angle of an arc is checked.</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>Interference check is disabled.</td>
</tr>
</tbody>
</table>

For the operation taken when the interference check shows the occurrence of an reference (overcutting), see the description of bit 5 (CAV) of parameter No. 19607.

NOTE
Checking of only the direction cannot be set.
When at least one of these parameters is set, the power must be turned off before operation is continued.

# 0  GSC  When the function for direct input of offset value measured B (T series) is used, an offset write input signal is input from:
0:  Machine side
1:  PMC side
When the interlock function for each axis direction is enabled (when bit 3 (DIT) of parameter No. 3003 is set to 0), switching can also be made between input from the machine side and input from PMC side for the interlock function for each axis direction.

# 4  TSD  In the function for direct input of offset value measured B (T series), the movement direction determination specifications:
0:  Do not apply.
1:  Apply.
This parameter is valid when four-contact input is used (bit 3 (TS1) of parameter No. 5004 is set to 0).
5010

Limit for ignoring the small movement resulting from cutter or tool nose radius compensation

- Setting input
- Real path
- mm, inch (input unit)
- Depend on the increment system of the reference axis
- 9 digit of minimum unit of data (refer to standard parameter setting table (A))
- (When the increment system is IS-B, -999999.999 to +999999.999)
- When the tool moves around a corner in cutter compensation or tool nose radius compensation mode, the limit for ignoring the small travel amount resulting from compensation is set. This limit eliminates the interruption of buffering caused by the small travel amount generated at the corner and any change in feedrate due to the interruption.

5020

Tool offset number used with the function for direct input of offset value measured B

- Parameter input
- Word path
- 0 to number of tool compensation values
- Set a tool offset number used with the function for direct input of offset value measured B (T series) (when a workpiece coordinate system shift amount is set). (Set the tool offset number corresponding to a tool under measurement beforehand.) This parameter is valid when automatic tool offset number selection is not performed (when bit 5 (QNI) of parameter No. 5005 is set to 0).
5024  Number of tool compensation values

[Input type] Parameter input
[Data type] Word path
[Valid data range] 0 to number of tool compensation values

Set the maximum allowable number of tool compensation values used for each path.

Ensure that the total number of values set in parameter No. 5024 for the individual paths is within the number of compensation values usable in the entire system.

If the total number of values set in parameter No. 5024 for the individual paths exceeds the number of compensation values usable in the entire system, or 0 is set in parameter No. 5024 for all paths, the number of compensation values usable for each path is a value obtained by dividing the number of compensation values usable in the entire system by the number of paths.

Tool compensation values as many as the number of compensation values used for each path are displayed on the screen. If tool compensation numbers more than the number of compensation values usable for each path are specified, an alarm is issued.

For example, 100 tool compensation sets are used, 120 sets may be allocated to path 1 and 80 sets to path 2. All of 200 sets need not be used.

NOTE
When this parameter is set, the power must be turned off before operation is continued.
### 5028

<table>
<thead>
<tr>
<th>Input type</th>
<th>Parameter input</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>Byte path</td>
</tr>
<tr>
<td>Valid data range</td>
<td>0 to 3</td>
</tr>
</tbody>
</table>

Specify the number of digits of a T code portion that is used for a tool offset number (wear offset number when the tool geometry/wear compensation function is used).

When 0 is set, the number of digits is determined by the number of tool compensation values.

- When the number of tool compensation values is 1 to 9: Lower 1 digit
- When the number of tool compensation values is 10 to 99: Lower 2 digits
- When the number of tool compensation values is 100 to 200: Lower 3 digits

**Example:**
When an offset number is specified using the lower 2 digits of a T code, set 2 in parameter No. 5028.

```
Txxxxxx yy
xxxxxx : Tool selection
yy : Tool offset number
```

**NOTE**
A value longer than the setting of parameter No. 3032 (allowable number of digits of a T code) cannot be set.
5029  Number of tool compensation value memories common to paths

NOTE
When this parameter is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Word
[Valid data range] 0 to number of tool compensation values

When using memories common to paths, set the number of common tool compensation values in this parameter.
Ensure that the setting of this parameter does not exceed the number of tool compensation values set for each path (parameter No. 5024).

[Example 1]
When parameter No. 5029 = 10, parameter No. 5024 (path 1) = 15, and parameter No. 5024 (path 2) = 30 in a 2-path system, tool compensation numbers 1 to 10 of all paths are made common.

[Example 2]
When parameter No. 5029 = 20 and the other conditions are the same as for Example 1, tool compensation numbers 1 to 15 are made common.

NOTE
1 Ensure that the setting of parameter No. 5029 does not exceed the number of tool compensation values for each path (parameter No. 5024). If the setting of parameter No. 5029 exceeds the number of compensation values of a path, the least of the numbers of compensation values in all paths is made common.
2 When 0 or a negative value is set, memories common to paths are not used.

**NOTE**

This parameter is valid when tool geometry/wear compensation is enabled (bit 6 (NGW) of parameter No. 8136 is 0).

---

# 0  OWD

In radius programming (bit 1 (ORC) of parameter No. 5004 is set to 1),

0: Tool offset values of both geometry compensation and wear compensation are specified by radius.

1: Tool offset value of geometry compensation is specified by radius and tool offset value of wear compensation is specified by diameter, for an axis of diameter programming.

---

**NOTE**

When at least one of these parameters is set, the power must be turned off before operation is continued.

---

# 0  OFA

# 1  OFC

These bits are used to specify the increment system and valid data range of a tool offset value.

</tr>
</tbody>
</table>
### 5043

[Input type] Parameter input  
[Data type] Byte path  
[Valid data range] 0 to Number of controlled axes  

Set the number of an axis for which the tool offset is corrected.  
If 0 or a value beyond the valid data range is set, the Y-axis offset is applied to the Y-axis of the basic three axes. If setting is made for the X- or Z-axis of the basic three axes, the standard tool offset for the X- or Z-axis is not used, and only the Y-axis offset is used.

### 5101

<table>
<thead>
<tr>
<th>#7</th>

<td></td>
<td></td>
<td></td>
<td>RTR</td>
<td></td>
<td>FXY</td>
</tr>
</tbody>
</table>

[Input type] Parameter input  
[Data type] Bit path  

**# 0  FXY**  
The drilling axis in the drilling canned cycle, or cutting axis in the grinding canned cycle is:  
0: In case of the Drilling canned cycle:  
Z-axis at all times.  
In case of the Grinding canned cycle:  
Z-axis at all times.  
1: Axis selected by the program

**NOTE**  
1 In the case of the T series, this parameter is valid only for the drilling canned cycle in the Series 10/11 format.  
2 When this parameter is 1, the drilling axis determined by plane selection (G17/G18/G19) in the drilling canned cycle in the T series 10/11 format. Therefore, the Y-axis is required to specify G17/G19.

**# 2  RTR**  
G83 and G87  
0: Specify a high-speed peck drilling cycle  
1: Specify a peck drilling cycle
# 2  QSR  Before a multiple repetitive canned cycle (G70 to G73) (T series) is started, a check to see if the program contains a block that has the sequence number specified in address Q is:
0: Not made.
1: Made.
When 1 is set in this parameter and the sequence number specified in address Q is not found, the alarm (PS0063) is issued and the canned cycle is not executed.

# 3  F0C  When the Series 10/11 format is used (with bit 1 (FCV) of parameter No.0001 set to 1), a canned drilling cycle is specified using:
0: Series 10/11 format
1: Series 0 format. However, the number of repetitions is specified using address L.

# 6  RAB  When a canned drilling cycle using the Series 10/11 format is specified (with bit 1 (FCV) of parameter No. 0001 set to 1 and bit 3 (F0C) of parameter No. 5102 set to 0), address R specifies:
0: Increment command.
1: Absolute command with G code system A. With G code system B or C, G90 and G91 are followed.

# 7  RDI  When a canned drilling cycle using the Series 10/11 format is specified (with bit 1 (FCV) of parameter No. 0001 set to 1 and bit 3 (F0C) of parameter No. 5102 set to 0), address R is based on:
0: Radius specification.
1: Diameter/radius specification of the drilling axis.
# 2  FCK  
In a multiple repetitive canned cycle (G71/G72) (T series), the machining profile is:
0:  Not checked.
1:  Checked.
The target figure specified by G71 or G72 is checked for the following:

- If the start point of the canned cycle is less than the maximum value of the machining profile even when the plus sign is specified for a finishing allowance, the alarm (PS0322) is issued.
- If the start point of the canned cycle is greater than the minimum value of the machining profile even when the minus sign is specified for a finishing allowance, the alarm (PS0322) is issued.
- If an unmonotonous command of type I is specified for the axis in the cutting direction, the alarm (PS0064 or PS0329) is issued.
- If an unmonotonous command is specified for the axis in the roughing direction, the alarm (PS0064 or PS0329) is issued.
- If the program does not include a block that has a sequence number specified by address Q, the alarm (PS0063) is issued.
  This check is made, regardless of bit 2 (QSR) of parameter No. 5102.
- If a command (G41/G42) on the blank side in tool nose radius compensation is inadequate, the alarm (PS0328) is issued.

# 0  SBC  In each of a drilling canned cycle, chamfering/corner rounding cycle, and optional-angle chamfering/corner rounding (T series) cycle:
0:  A single block stop is not carried out.
1:  A single block stop is carried out.

# 1  RF1  In a multiple repetitive canned cycle (G71/G72) (T series) of type I, roughing is:
0:  Performed.
1:  Not performed.

**NOTE**

When a roughing allowance (\(\Delta i/\Delta k\)) is specified using the Series 10/11 program format, roughing is performed, regardless of the setting of this parameter.
# 2  RF2  In a multiple repetitive canned cycle (G71/G72) (T series) of type II, roughing is:
0:  Performed.
1:  Not performed.

NOTE
When a roughing allowance (Δi/Δk) is specified using the Series 10/11 program format, roughing is performed, regardless of the setting of this parameter.

# 3  M5T  When the rotation direction of the spindle is changed from forward rotation to reverse rotation or from reserve rotation to forward rotation in a tapping cycle (G84/G88):
0:  M05 is output before output of M04 or M03.
1:  M05 is not output before output of M04 or M03.

NOTE
1  This parameter is equivalent to bit 6 (M5T) of parameter No. 5101 of the FS0i-C.
2  For the T series, the logical level (0/1) is opposite to that of the FS0i-C.

#7 #6 #5 #4 #3 #2 #1 #0
5106  GFX

[Input type] Parameter input
[Data type] Bit path

NOTE
When this parameter is set, the power must be turned off before operation is continued.

# 0  GFX  When grinding canned cycle option is specified, the G71, G72, G73, or G74 command is:
0:  A multiple repetitive canned cycle (T series) command.
1:  A grinding canned cycle command.

5110  M code for C-axis clamping in a drilling canned cycle

[Input type] Parameter input
[Data type] 2-word path
[Valid data range] 0 to 99999998
This parameter sets an M code for C-axis clamping in a drilling canned cycle.
**5111**

Dwell time when C-axis unclamping is specified in drilling canned cycle

- **Input type**: Parameter input
- **Data type**: 2-word path
- **Valid data range**: 0 to 32767
- **Unit of data**: Increment system IS-A IS-B IS-C Unit

<table>
<thead>
<tr>
<th>Increment system</th>
<th>IS-A</th>
<th>IS-B</th>
<th>IS-C</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>10</td>
<td>1</td>
<td>0.1</td>
<td>msec</td>
</tr>
</tbody>
</table>

(The increment system does not depend on whether inch input or metric input is used.)

This parameter sets the dwell time when C-axis unclamping is specified in a drilling canned cycle.

**5114**

Return value of high-speed peck drilling cycle

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the reference axis
- **Valid data range**: 9 digit of minimum unit of data (refer to standard parameter setting table (A))

(When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets the return value in high-speed peck drilling cycle.

G83 (T series, when the parameter RTR (No.5101#2) is set to 0)

- q: Depth of cut
- d: Return value
- R point
- Z point
**5115**

**Clearance value in a peck drilling cycle**

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the reference axis
- **Valid data range**: 9 digit of minimum unit of data (refer to standard parameter setting table (A))
  
  (When the increment system is IS-B, -999999.999 to +999999.999)

This parameter sets a clearance value in a peck drilling cycle.

**5130**

**Cutting value (chamfering value) in thread cutting cycles G92 and G76**

- **Input type**: Parameter input
- **Data type**: Byte path
- **Unit of data**: 0.1
- **Valid data range**: 0 to 127

This parameter sets a cutting value (chamfering value) in the thread cutting cycle (G76) of a multiple repetitive canned cycle (T series) and in the thread cutting cycle (G92) of a canned cycle.

Let L b a lead. Then, a cutting value range from 0.1L to 12.7L is allowed.

To specify a cutting value of 10.0L, for example, specify 100 in this parameter.

**5131**

**Cutting angle in thread cutting cycles G92 and G76**

- **Input type**: Parameter input
- **Data type**: Byte path
- **Unit of data**: Degree
- **Valid data range**: 1 to 89

This parameter sets the cutting angle in the thread cutting cycle (G76) of a multiple repetitive canned cycle (T series) and in the thread cutting cycle (G92) of a canned cycle.

When 0 is set, an angle of 45 degrees is specified.
5132

Depth of cut in multiple repetitive canned cycles G71 and G72

- Parameter input
- Real path
- mm, inch (input unit)
- Depend on the increment system of the reference axis
- 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
- (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the depth of cut in multiple repetitive canned cycles G71 and G72 (T series).

This parameter is not used with the Series 10/11 program format.

**NOTE**
Specify a radius value at all times.

5133

Escape in multiple repetitive canned cycles G71 and G72

- Parameter input
- Real path
- mm, inch (input unit)
- Depend on the increment system of the reference axis
- 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
- (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the escape in multiple repetitive canned cycles G71 and G72 (T series).

**NOTE**
Specify a radius value at all times.

5134

Clearance value in multiple repetitive canned cycles G71 and G72

- Parameter input
- Real path
- mm, inch (input unit)
- Depend on the increment system of the reference axis
- 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
- (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets a clearance value up to the cutting feed start point in multiple repetitive canned cycles (G71/G72) (T series).

**NOTE**
Specify a radius value at all times.
### 5135 Retraction distance in the multiple repetitive canned cycle G73 (second axis on the plane)

- **Input type:** Parameter input
- **Data type:** Real path
- **Unit of data:** mm, inch (input unit)
- **Minimum unit of data:** Depend on the increment system of the reference axis
- **Valid data range:** 9 digit of minimum unit of data (refer to standard parameter setting table (A))

This parameter sets a retraction distance along the second axis on the plane in the multiple repetitive canned cycle G73 (T series). This parameter is not used with the Series 10/11 program format.

**NOTE**
Specify a radius value at all times.

### 5136 Retraction distance in the multiple repetitive canned cycle G73 (first axis on the plane)

- **Input type:** Parameter input
- **Data type:** Real path
- **Unit of data:** mm, inch (input unit)
- **Minimum unit of data:** Depend on the increment system of the reference axis
- **Valid data range:** 9 digit of minimum unit of data (refer to standard parameter setting table (A))

This parameter sets a retraction distance along the first axis on the plane in the multiple repetitive canned cycle G73 (T series). This parameter is not used with the Series 10/11 program format.

**NOTE**
Specify a radius value at all times.

### 5137 Number of divisions in the multiple repetitive canned cycle G73

- **Input type:** Parameter input
- **Data type:** 2-word path
- **Unit of data:** Cycle
- **Valid data range:** 1 to 99999999

This parameter sets the number of divisions in the multiple repetitive canned cycle G73 (T series). This parameter is not used with the Series 10/11 program format.
### 5139 Return in multiple repetitive canned cycles G74 and G75

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the reference axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
  - (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the return in multiple repetitive canned cycles G74 and G75 (T series).

**NOTE**
Specify a radius value at all times.

### 5140 Minimum depth of cut in the multiple repetitive canned cycle G76

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the reference axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
  - (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets a minimum depth of cut in the multiple repetitive canned cycle G76 (T series) so that the depth of cut does not become too small when the depth of cut is constant.

**NOTE**
Specify a radius value at all times.

### 5141 Finishing allowance in the multiple repetitive canned cycle G76

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the reference axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
  - (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the finishing allowance in multiple repetitive canned cycle G76 (T series).

**NOTE**
Specify a radius value at all times.
5142  Repetition count of final finishing in multiple repetitive canned cycle G76

[Input type] Parameter input
[Data type] 2-word path
[Unit of data] Cycle
[Valid data range] 1 to 99999999

This parameter sets the number of final finishing cycle repeats in the multiple repetitive canned cycle G76 (T series). When 0 is set, only one final finishing cycle is executed.

5143  Tool nose angle in multiple repetitive canned cycle G76

[Input type] Parameter input
[Data type] Byte path
[Unit of data] Degree
[Valid data range] 0, 29, 30, 55, 60, 80

This parameter sets the tool nose angle in multiple repetitive canned cycle G76 (T series). This parameter is not used with the Series 10/11 program format.
Applicable to multiple repetitive canned cycles G71 and G72 (5145)

<table>
<thead>
<tr>
<th>Parameter input</th>
</tr>
</thead>

<tr>
<td>(When the increment system is IS-B, 0.0 to +999999.999)</td>
</tr>
<tr>
<td>If a monotonous command of type I or II is not specified for the axis in the roughing direction, the alarm (PS0064 or PS0329) is issued. When a program is created automatically, a very small unmonotonous figure may be produced. Set an unsigned allowable value for such an unmonotonous figure. By doing so, G71 and G72 cycles can be executed even in a program including unmonotonous figure. Example)</td>
</tr>
<tr>
<td>Suppose that a G71 command where the direction of the cutting axis (X-axis) is minus and the direction of the roughing axis (Z-axis) is minus is specified. In such a case, when an unmonotonous command for moving 0.001 mm in the plus direction along the Z-axis is specified in a target figure program, roughing can be performed according to the programmed figure without an alarm by setting 0.001 mm in this parameter.</td>
</tr>
</tbody>
</table>

**NOTE**

A check for a monotonous figure is made at all times during G71 and G72 cycles. A figure (programmed path) is checked. When tool nose radius compensation is performed, a path after compensation is checked. When bit 2 (FCK) of parameter No. 5104 is set to 1, a check is made before G71 or G72 cycle operation. In this case, not a path after tool nose radius compensation but a programmed path is checked. Note that no alarm is issued when an allowable value is set.

Use a radius value to set this parameter at all times.
Allowable value 2 in multiple repetitive canned cycles G71 and G72

[Input type] Parameter input
[Data type] Real path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the reference axis
[Valid data range] 0 to cut of depth

If a monotonous command of type I is not specified for the axis in the cutting direction, the alarm (PS0064 or PS0329) is issued. When a program is created automatically, a very small unmonotonous figure may be produced. Set an unsigned allowable value for such an unmonotonous figure. By doing so, G71 and G72 cycles can be executed even in a program including an unmonotonous figure. The allowable value is clamped to the depth of cut specified by a multiple repetitive canned cycle.

Example)
Suppose that a G71 command where the direction of the cutting axis (X-axis) is minus and the direction of the roughing axis (Z-axis) is minus is specified. In such a case, when an unmonotonous command for moving 0.001 mm in the minus direction along the X-axis is specified in a target figure program for moving from the bottom of cutting to the end point, roughing can be performed according to the programmed figure without an alarm by setting 0.001 mm in this parameter.

NOTE
A check for a monotonous figure is made at all times during G71 and G72 cycles. A figure (programmed path) is checked. When tool nose radius compensation is performed, a path after compensation is checked. When bit 2 (FCK) of parameter No. 5104 is set to 1, a check is made before G71 or G72 cycle operation. In this case, not a path after tool nose radius compensation but a programmed path is checked.
Note that no alarm is issued when an allowable value is set.
Use a radius value to set this parameter at all times.
5176  Grinding axis number in Traverse Grinding Cycle(G71)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes
Set the Grinding axis number of Traverse Grinding Cycle(G71).

**NOTE**
The axis number except for the cutting axis can be specified. When the axis number which is same to cutting axis is specified, PS0456 alarm is issued at the time of execution. The Grinding Cycle is executed when this parameter value is 0, PS0456 alarm is also issued.

5177  Grinding axis number of Traverse direct constant-size Grinding cycle(G72)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes
Set the Grinding axis number of Traverse direct constant-size Grinding cycle(G72).

**NOTE**
The axis number except for the cutting axis can be specified. When the axis number which is same to cutting axis is specified, PS0456 alarm is issued at the time of execution. The Grinding Cycle is executed when this parameter value is 0, PS0456 alarm is also issued.

5178  Grinding axis number of Oscillation Grinding Cycle(G73)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes
Set the Grinding axis number of Oscillation Grinding Cycle(G73).

**NOTE**
The axis number except for the cutting axis can be specified. When the axis number which is same to cutting axis is specified, PS0456 alarm is issued at the time of execution. The Grinding Cycle is executed when this parameter value is 0, PS0456 alarm is also issued.
5179 Grinding axis number of Oscillation Direct Fixed Dimension Grinding Cycle(G74)

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 0 to Number of controlled axes

Set the Grinding axis number of Oscillation Direct Fixed Dimension Grinding Cycle(G74).

NOTE
The axis number except for the cutting axis can be specified. When the axis number which is same to cutting axis is specified, PS0456 alarm is issued at the time of execution. The Grinding Cycle is executed when this parameter value is 0, PS0456 alarm is also issued.

5200 FHD PCP DOV G84

[Input type] Parameter input
[Data type] Bit path

#0 G84 Method for specifying rigid tapping:
0: An M code specifying the rigid tapping mode is specified prior to the issue of the G84 (or G74) command. (See parameter No.5210).
1: An M code specifying the rigid tapping mode is not used. (G84 cannot be used as a G code for the tapping cycle; G74 cannot be used for the reverse tapping cycle.)

#4 DOV Override during extraction in rigid tapping:
0: Invalidated
1: Validated (The override value is set in parameter No.5211.)

#5 PCP Address Q is specified in a tapping cycle/ rigid tapping:
0: A high-speed peck tapping cycle is assumed.
1: A peck tapping cycle is assumed.

NOTE
In a tapping cycle, this parameter is valid when bit 6 (PCT) of parameter No. 5104 is 1. When bit 6 (PCT) of parameter No. 5104 is 0, a (high-speed) peck tapping cycle is not assumed.

#6 FHD Feed hold and single block in rigid tapping:
0: Invalidated
1: Validated
# 2 TDR Cutting time constant in rigid tapping:
0: Uses a same parameter during cutting and extraction (Parameter Nos. 5261 through 5264)
1: Not use a same parameter during cutting and extraction
Parameter Nos. 5261 to 5264: Time constant during cutting
Parameter Nos. 5271 to 5274: Time constant during extraction

# 3 OVU The increment unit of the override parameter (No.5211) for tool rigid tapping extraction is:
0: 1%
1: 10%

# 4 OV3 A spindle speed for extraction is programmed, so override for extraction operation is:
0: Disabled.
1: Enabled.

# 6 OVE The specification range of extraction override command (address J) by rigid tapping program specification is:
0: 100% to 200%.
1: 100% to 2000%.

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

NOTE
1 To enable the extraction override command (address J) by program specification, set bit 4 (OV3) of parameter No.5201 to 1.
2 When this parameter is set to 1, the operation equivalent to that of the FS0i-C is assumed.
# 2  RFF In rigid tapping, feed forward is:
0: Disabled.
1: Enabled. (Recommended)

As the standard setting, set 1.
At the same time, set the parameter for the advanced preview feed forward coefficient for the tapping axis and the parameter for the advance preview feed forward coefficient for the spindle so that these values match.
- Advanced preview feed forward coefficient for the tapping axis:
  Parameter No.2092
  (or parameter No.2144 if the cutting/rapid traverse feed forward function is enabled (bit 4 of parameter No.2214 is set to 1))
- Advanced preview feed forward coefficient for the spindle:
  Parameter No.4344

NOTE
This parameter is valid when a serial spindle is used.

# 4  OVS In rigid tapping, override by the feedrate override select signal and cancellation of override by the override cancel signal is:
0: Disabled.
1: Enabled.

When feedrate override is enabled, extraction override is disabled.
The spindle override is clamped to 100% during rigid tapping, regardless of the setting of this parameter.

NOTE
This parameter becomes invalid when bit 1 (FCV) of parameter No.0001 is set to 1, and rigid tapping is specified using the Series10/11 format.
### 5211 Override value during rigid tapping extraction

- **Input type**: Parameter input
- **Data type**: Word path
- **Unit of data**: 1% or 10%
- **Valid data range**: 0 to 200

The parameter sets the override value during rigid tapping extraction.

**NOTE**

The override value is valid when bit 4 (DOV) of parameter No.5200 is set to 1. When bit 3 (OVU) of parameter No.5201 is set to 1, the unit of set data is 10%. An override of up to 200% can be applied to extraction.

### 5213 Return or clearance in peck tapping cycle

- **Input type**: Setting input
- **Data type**: Real path
- **Unit of data**: mm, inch (input unit)
- **Minimum unit of data**: Depend on the increment system of the drilling axis
- **Valid data range**: 0 or positive 9 digit of minimum unit of data (refer to the standard parameter setting table (B))
  - (When the increment system is IS-B, 0.0 to +999999.999)

This parameter sets the escape value of a high-speed peck tapping cycle or the clearance value of a peck tapping cycle.

<table>
<thead>
<tr>
<th>When the parameter PCP (bit 5 of No.5200) is set to 0.</th>
<th>When the parameter PCP (bit 5 of No.5200) is set to 1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>q</td>
<td>q</td>
</tr>
<tr>
<td>d</td>
<td>d</td>
</tr>
</tbody>
</table>

**NOTE**

1. In a tapping cycle, this parameter is valid when bit 6 (PCT) of parameter No. 5104 is 1.
2. For the diameter axis, set this parameter using the diameter value.
5241  Maximum spindle speed in rigid tapping (first gear)

5242  Maximum spindle speed in rigid tapping (second gear)

5243  Maximum spindle speed in rigid tapping (third gear)

5244  Maximum spindle speed in rigid tapping (fourth gear)

[Input type] Parameter input
[Data type] 2-word spindle
[Unit of data] min⁻¹
[Valid data range] 0 to 9999

Spindle position coder gear ratio
1 : 1  0 to 7400
1 : 2  0 to 9999
1 : 4  0 to 9999
1 : 8  0 to 9999

Each of these parameters is used to set a maximum spindle speed for each gear in rigid tapping.
Set the same value for both parameter No.5241 and parameter No.5243 for a one-stage gear system. For a two-stage gear system, set the same value as set in parameter No. 5242 in parameter No. 5243. Otherwise, alarm PS0200 will be issued.

5321  Spindle backlash in rigid tapping (first-stage gear)

5322  Spindle backlash in rigid tapping (second-stage gear)

5323  Spindle backlash in rigid tapping (third-stage gear)

5324  Spindle backlash in rigid tapping (fourth-stage gear)

[Input type] Parameter input
[Data type] Word spindle
[Unit of data] Detection unit
[Valid data range] -9999 to 9999

Each of these parameters is used to set a spindle backlash.

5450  PLS  PDI

[Input type] Parameter input
[Data type] Bit path

# 0  PDI  When the second axis on the plane in the polar coordinate interpolation mode is based on radius specification:
0:  Radius specification is used.
1:  Diameter specification is used.
# 2 PLS

The polar coordinate interpolation shift function is:

0: Not used.
1: Used.

This enables machining using the workpiece coordinate system with a desired point which is not the center of the rotation axis set as the origin of the coordinate system in polar coordinate interpolation.

5460

Axis (linear axis) specification for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes

This parameter sets control axis numbers of linear axis to execute polar interpolation.

5461

Axis (rotation axis) specification for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Valid data range] 1 to number of controlled axes

This parameter sets control axis numbers of rotation axis to execute polar interpolation.

5463

Automatic override tolerance ratio for polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Unit of data] %
[Valid data range] 0 to 100

Typical setting: 90% (treated as 90% when set to 0)

Set the tolerance ratio of the fastest cutting feedrate to the speed of the rotation axis during automatic override of polar coordinate interpolation.

5464

Compensation for error on hypothetical axis of polar coordinate interpolation

[Input type] Parameter input
[Data type] Byte path
[Unit of data] mm, inch (input unit)
[Minimum unit of data] Depend on the increment system of the reference axis
[Valid data range] 9 digit of minimum unit of data (refer to standard parameter setting table (A))

(For IS-B, -999999.999 to +999999.999)

This parameter is used to set the error if the center of the rotation axis on which polar coordinate interpolation is performed is not on the X-axis.

If the setting of the parameter is 0, regular polar coordinate interpolation is performed.
### [6000] #7 #6 #5 #4 #3 #2 #1 #0

[Input type] Parameter input  
[Data type] Bit path

#### #1 MGO
When a GOTO statement for specifying custom macro control is executed, a high-speed branch to 20 sequence numbers executed from the start of the program is:
- **0**: A high-speed branch is not caused to n sequence numbers from the start of the executed program.
- **1**: A high-speed branch is caused to n sequence numbers from the start of the program.

#### #4 HGO
When a GOTO statement in a custom macro control command is executed, a high-speed branch to the 30 sequence numbers immediately before the executed statement is:
- **0**: Not made.
- **1**: Made.

### [6240] #7 #6 #5 #4 #3 #2 #1 #0

[Input type] Parameter input  
[Data type] Bit path

**NOTE**
When at least one of these parameters is set, the power must be turned off before operation is continued.

#### #0 AE0
Measurement position arrival is assumed when the automatic tool compensation signals XAE1 and XAE2 <X004.0, 1> (T series) or the automatic tool length measurement signals XAE1, XAE2, and XAE3 <X004.0, .1, .2> (M series) are:
- **0**: 1.
- **1**: 0.

#### #7 IGA
Automatic tool compensation (T series) is:
- **0**: Used.
- **1**: Not used.
### APPENDIX A. PARAMETERS

#### 6241
Feedrate during measurement of automatic tool compensation (T series) (for the XAE1 and GAE1 signals)

- **Input type**: Parameter input
- **Data type**: Real path
- **Unit of data**: mm/min, inch/min, deg/min (machine unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: Refer to the standard parameter setting table (C) (When the increment system is IS-B, 0.0 to +999000.0)

These parameters set the relevant feedrate during measurement of automatic tool compensation (T series).

**NOTE**
When the setting of parameter No. 6242 or 6243 is 0, the setting of parameter No. 6241 is used.

#### 6242
Feedrate during measurement of automatic tool compensation (T series) (for the XAE2 and GAE2 signals)

#### 6251
\( \gamma \) value on the X axis during automatic tool compensation (T series)

- **Input type**: Parameter input
- **Data type**: 2-word path
- **Unit of data**: mm, inch, deg (machine unit)
- **Minimum unit of data**: Depend on the increment system of the applied axis
- **Valid data range**: 9 digit of minimum unit of data (refer to standard parameter setting table (A)) (When the increment system is IS-B, -999999.999 to +999999.999)

These parameters set the relevant \( \gamma \) value during automatic tool compensation (T series).

**NOTE**
Set a radius value regardless of whether diameter or radius programming is specified.

#### 6252
\( \gamma \) value on the Z axis during automatic tool compensation (T series)
6254 | ε value on the X axis during automatic tool compensation (T series)

6255 | ε value on the Z axis during automatic tool compensation (T series)

**[Input type]** Parameter input  
**[Data type]** 2-word path  
**[Unit of data]** mm, inch, deg (machine unit)  
**[Minimum unit of data]** Depend on the increment system of the applied axis  
**[Valid data range]** 9 digit of minimum unit of data (refer to standard parameter setting table (A))  
(When the increment system is IS-B, -999999.999 to +999999.999)  
These parameters set the relevant ε value during automatic tool compensation (T series).

**NOTE**  
Set a radius value regardless of whether diameter or radius programming is specified.

8103 | MWT
---
#7 | #6 | #5 | #4 | #3 | #2 | #1 | #0

**[Input type]** Parameter input  
**[Data type]** Bit  
**NOTE**  
When this parameter is set, the power must be turned off before operation is continued.

# 0  MWT  
As the signal interface for the waiting M code:
0: The path individual signal interface is used.  
1: The path common signal interface is used.  
This parameter can be selected only when 2-path control is used.

8110 | Waiting M code range (minimum value)

8111 | Waiting M code range (maximum value)

**[Input type]** Parameter input  
**[Data type]** 2-word  
**[Valid data range]** 0,100 to 99999999  
A range of M code values can be set by specifying a minimum waiting M coder value (parameter No. 8110) and a maximum waiting M code value (parameter No. 8111).  
(parameter No. 8110) ≤ (waiting M code) ≤ (parameter No. 8111)  
Set 0 in these parameters when the waiting M code is not used.
### #8132 YOF

**NOTE**
When at least one of these parameters is set, the power must be turned off before operation is continued.

</table>
NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#  1  BAR
Chuck and tail stock barrier function (T series) is:
0: Not Used.
1: Used.

NOTE
1 The chuck and tail stock barrier function is provided only for the T series.
2 When the chuck and tail stock barrier function is selected, stored stroke limits 2 and 3 cannot be used.

That is, this parameter also specifies whether to use stored stroke limits 2 and 3 as shown below.

BAR Stored stroke limits 2 and 3 are:
0: Used.
1: Not Used.

#  2  CCR
Chamfering / corner R is:
0: Not Used.
1: Used.

NOTE
When at least one of these parameters is set, the power must be turned off before operation is continued.

[Input type] Parameter input
[Data type] Bit

#  6  NGW
Tool geometry/wear compensation (T series) is:
0: Used.
1: Not Used.
[Input type] Parameter input  
[Data type] Bit path  

# 2  CCC  
In the cutter compensation/tool nose radius compensation mode, the outer corner connection method is based on:  
0: Linear connection type.  
1: Circular connection type.  

# 5  CAV  
When an interference check finds that interference (overcutting) occurred:  
0: Machining stops with the alarm (PS0041).  
   (Interference check alarm function)  
1: Machining is continued by changing the tool path to prevent interference (overcutting) from occurring. (Interference check avoidance function)  
For the interference check method, see the descriptions of bit 1 (CNC) of parameter No. 5008 and bit 3 (CNV) of parameter No. 5008.  

# 6  NAA  
When the interference check avoidance function considers that an avoidance operation is dangerous or that a further interference to the interference avoidance vector occurs:  
0: An alarm is issued.  
   When an avoidance operation is considered to be dangerous, the alarm (PS5447) is issued.  
   When a further interference to the interference avoidance vector is considered to occur, the alarm (PS5448) is issued.  
1: No alarm is issued, and the avoidance operation is continued.  

⚠️ CAUTION  
When this parameter is set to 1, the path may be shifted largely. Therefore, set this parameter to 0 unless special reasons are present.
19625  Number of blocks to be read in the cutter compensation/tool nose radius compensation mode

[Input type] Setting input
[Data type] Byte path
[Valid data range] 3 to 8

This parameter sets the number of blocks to be read in the cutter compensation/tool nose radius compensation mode. When a value less than 3 is set, the specification of 3 is assumed. When a value greater than 8 is set, the specification of 8 is assumed. As a greater number of blocks are read, an overcutting (interference) forecast can be made with a command farther ahead. However, the number of blocks read and analyzed increases, so that a longer block processing time becomes necessary.

Even if the setting of this parameter is modified in the MDI mode by stopping in the cutter compensation/tool nose radius compensation mode, the setting does not become valid immediately. Before the new setting of this parameter can become valid, the cutter compensation/tool nose radius compensation mode must be canceled, then the mode must be entered again.
### A.2 DATA TYPE

Parameters are classified by data type as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Valid data range</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit</td>
<td>0 or 1</td>

</tbody>
</table>

**NOTE**

1. Each of the parameters of the bit, bit machine group, bit path, bit axis, and bit spindle types consists of 8 bits for one data number (parameters with eight different meanings).
2. For machine group types, parameters corresponding to the maximum number of machine groups are present, so that independent data can be set for each machine group.
3. For path types, parameters corresponding to the maximum number of paths are present, so that independent data can be set for each path.
4. For axis types, parameters corresponding to the maximum number of control axes are present, so that independent data can be set for each control axis.
5. For spindle types, parameters corresponding to the maximum number of spindles are present, so that independent data can be set for each spindle axis.
6. The valid data range for each data type indicates a general range. The range varies according to the parameters. For the valid data range of a specific parameter, see the explanation of the parameter.
This section defines the standard minimum data units and valid data ranges of the CNC parameters of the real type, real machine group type, real path type, real axis type, and real spindle type. The data type and unit of data of each parameter conform to the specifications of each function.

**NOTE**
1. Values are rounded up or down to the nearest multiples of the minimum data unit.
2. A valid data range means data input limits, and may differ from values representing actual performance.
3. For information on the ranges of commands to the CNC, refer to Appendix D, "Range of Command Value."

(A) Length and angle parameters (type 1)

<td>0.000 to +999000.0000</td>
</tr>
<tr>
<td>degree/min</td>
<td>IS-C 0.0001</td>
<td>0.0000</td>
<td>0.0000 to +9600.0000</td>
</tr>
</tbody>
</table>

(D) Acceleration and angular acceleration parameters

<table>
<thead>
<tr>
<th>Unit of data</th>
<th>Increment system</th>
<th>Minimum data unit</th>
<th>Valid data range</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm/sec²</td>
<td>IS-A 0.01</td>
<td>0.00</td>
<td>0.00 to +9999999.99</td>
</tr>
<tr>
<td>deg./sec²</td>
<td>IS-B 0.001</td>
<td>0.000</td>
<td>0.000 to +9999999.999</td>
</tr>
<tr>
<td></td>
<td>IS-C 0.0001</td>
<td>0.0000</td>
<td>0.0000 to +9999999.9999</td>
</tr>
<tr>
<td>inch/sec²</td>
<td>IS-A 0.001</td>
<td>0.000</td>
<td>0.000 to +9999999.999</td>
</tr>
<tr>
<td></td>
<td>IS-B 0.0001</td>
<td>0.0000</td>
<td>0.0000 to +9999999.9999</td>
</tr>
<tr>
<td></td>
<td>IS-C 0.00001</td>
<td>0.00000</td>
<td>0.00000 to +9999999.9999</td>
</tr>
</tbody>
</table>

If bit 7 (IESP) of parameter No. 1013 is set to 1, the valid data ranges for IS-C are extended as follows:

<table>
<thead>
<tr>
<th>Unit of data</th>
<th>Increment system</th>
<th>Minimum data unit</th>
<th>Valid data range</th>

B.1.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diameter/radius specification in the move command for each axis</td>
<td>- Make a selection using bit 3 (DIAx) of parameter No. 1006.</td>
</tr>
</tbody>
</table>

**Bit 3 (DIAx) of parameter No. 1006**
The move command for each axis specifies:
0: Radius.
1: Diameter.

With Series 0i-C, in order for an axis whose diameter is specified to travel the specified distance, it is necessary not only to set 1 in bit 3 (DIAx) of parameter No. 1006 but also to make either of the following two changes:
- Reduce the command multiplier (CMR) to half. (The detection unit does not need to be changed.)
- Reduce the detection unit to half, and double the flexible feed gear (DMR).

With Series 0i-D, by contrast, just setting 1 in bit 3 (DIAx) of parameter No. 1006 causes the CNC to reduce the command pulses to half, eliminating the need to make the changes described above (when the detection unit is not changed).

Note that, when the detection unit is reduced to half, both the CMR and DMR need to be doubled.

B.1.2 Differences in Diagnosis Display

None.
## AUTOMATIC TOOL OFFSET

<td>- The processing is determined by the settings of bit 7 (WZR) of parameter No. 1201, bit 3 (RLC) of parameter No. 1202, bit 6 (CLR) of parameter No. 3402, and bit 6 (C14) of parameter No. 3407. Bit 5 (SNC) of parameter No. 1202 is not available.</td>
</tr>
<tr>
<td>Bit 3 (RLC) of parameter No. 1202</td>
<td>Upon reset, the local coordinate system is: 0: Not canceled. 1: Canceled.</td>
<td></td>
</tr>
<tr>
<td>Bit 5 (SNC) of parameter No. 1202</td>
<td>After servo alarm cancellation, the local coordinate system is: 0: Cleared. 1: Not cleared.</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>When the RLC bit of the parameter is set to 1, the local coordinate system is cleared, even if the SNC bit of the parameter is set to 1.</td>
<td><strong>NOTE</strong> When bit 6 (CLR) of parameter No. 3402 is set to 0, the G code of group number 14 (workpiece coordinate system) is: 0: Placed in the reset state. 1: Not placed in the reset state. <strong>NOTE</strong> When bit 6 (CLR) of parameter No. 3402 is set to 1, the processing depends on the setting of bit 6 (C14) of parameter No. 3407.</td>
</tr>
</tbody>
</table>

**Bit 7 (WZR) of parameter No. 1201**
If the CNC is reset by the reset key on the MDI panel, external reset signal, reset and rewind signal, or emergency stop signal when bit 6 (CLR) of parameter No. 3402 is set to 0, the G code of group number 14 (workpiece coordinate system) is:
0: Placed in the reset state.
1: Not placed in the reset state.

**NOTE** When bit 6 (CLR) of parameter No. 3402 is set to 1, the local coordinate system is canceled, regardless of the setting of this parameter.

**Bit 3 (RLC) of parameter No. 1202**
Upon reset, the local coordinate system is:
0: Not canceled.
1: Canceled.

**NOTE**
- When bit 6 (CLR) of parameter No. 3402 is set to 0 and bit 7 (WZR) of parameter No. 1201 is set to 1, the local coordinate system is canceled, regardless of the setting of this parameter.
- When bit 6 (CLR) of parameter No. 3402 is set to 1 and bit 6 (C14) of parameter No. 3407 is set to 0, the local coordinate system is canceled, regardless of the setting of this parameter.

**Bit 6 (CLR) of parameter No. 3402**
The reset key on the MDI panel, external reset signal, reset and rewind signal, or emergency stop signal places the local coordinate system in:
0: Reset state.
1: Clear state.

**Bit 6 (C14) of parameter No. 3407**
If the CNC is reset by the reset key on the MDI panel, external reset signal, reset and rewind signal, or emergency stop signal when bit 6 (CLR) of parameter No. 3402 is set to 1, the G code of group number 14 (workpiece coordinate system) is:
0: Placed in the clear state.
1: Not placed in the clear state.

### B.17 CUSTOM MACRO

#### B.17.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keep-type common variable (#500 to #999)</td>
<td>- The default value is &lt;null&gt;.</td>
<td>- The default value is 0.</td>
</tr>
<tr>
<td></td>
<td>- The Series 0i-D function (described at right) is not available.</td>
<td>- The range specified by parameter Nos. 6031 and 6032 can be made write-protected (read-only).</td>
</tr>
<tr>
<td>System variable to read machine coordinates #5021 to #5025</td>
<td>- Machine coordinates are always read in machine units (output units).</td>
<td>- Machine coordinates are always read in input units. Example) When the setting unit is IS-B, the input unit is the inch, the machine unit is the millimeter, and the coordinate value of the X axis (first axis) is as follows: Machine coordinate = 30.000 (mm) Since the value of #5021 is read in input units (inches), #5021 is 1.1811.</td>
</tr>
<tr>
<td>Logical operations in an if statement</td>
<td>- Logical operations can be used by setting 1 in bit 0 (MLG) of parameter No. 6006.</td>
<td>- Bit 0 (MLG) of parameter No. 6006 is not available. Logical operations can always be used.</td>
</tr>
</tbody>
</table>

**Bit 0 (MLG) of parameter No. 6006**

In an if statement in a custom macro, logical operations:

- 0: Cannot be used. (P/S alarm No. 114 is issued.)
- 1: Can be used.

Behavior of the GOTO statement when a sequence number is not found at the start of the block

- The command after the sequence number of the block (to the right of the sequence number) is executed.

* Use a sequence number at the start of a block.

Behavior of "GOTO 0" when there is a sequence number

- The program jumps to the block containing the sequence number. No jump occurs. Alarm PS1128 is issued.

* Do not use a sequence number.

When another NC command is found in a G65 block or in an M code block where a macro is called by an M code

- In a program like the one shown in the example, G01 changes the G code group to 01, while the move command X100. is not executed. X100. is regarded as an argument of G65.

- A program like the one shown in the example cannot be executed. Alarm PS0127 is issued. A G65 code or an M code that calls a macro must be specified at the beginning of a block (before all other arguments).
When the machine is run under the conditions and program described below:

**[Conditions]**
- Subprogram call by T code is enabled (bit 5 (TCS) of parameter No. 6001 is set to 1).
- The M code that calls subprogram No. 9001 is M06 (parameter No. 6071 is set to 6).

**[Program]**

```
O0001;
T100; (1)
M06 T200; (2)
T300 M06; (3)
M30;
```

In FS0i-C, blocks (1) to (3) of the program causes the machine to behave as follows:
1) Calls and executes O9000.
2) Outputs T200 and waits for FIN. Upon receipt of the FIN signal, the machine calls and executes O9001.
3) Outputs T300 and waits for FIN. Upon receipt of the FIN signal, the machine calls and executes O9001.

In FS0i-D, blocks (1) to (3) of the program causes the machine to behave as follows:
1) Calls and executes O9000.
2) Issues alarm PS1091.
3) Issues alarm PS1091 (when the program is run with block (2) deleted).

Using bit 4 (NPS) of parameter No. 3450, it is possible to select whether the block is treated as an NC statement or a macro statement.

**Bit 4 (NPS) of parameter No. 3450**

- 0: Treated as a single-block NC statement without movement. (Single block stop is performed.)
- 1: Treated as a macro statement. (Single block stop is not performed.)

Block containing "M98 Pxxxx" or "M99" without any addresses other than O, N, P, and L

Using bit 4 (NPS) of parameter No. 3450, it is possible to select whether the block is treated as an NC statement or a macro statement.

**Bit 4 (NPS) of parameter No. 3450**

- 0: Treated as a single-block NC statement without movement. (Single block stop is performed.)
- 1: Treated as a macro statement. (Single block stop is not performed.)

For details about macro and NC statements, refer to Section 16.4, "MACRO AND NC STATEMENTS", in "USER'S MANUAL" (B-64304EN).

- The call nesting level differs as follows.

<table>
<thead>
<tr>
<th>Model Call method</th>

<tr>
<td>Subprogram call (M98)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

- Make a selection using bit 7 (CLV) of parameter No. 6001.

**Bit 7 (CLV) of parameter No. 6001**

- Make a selection using bit 7 (CLV) of parameter No. 6001.

- Bit 7 (CLV) of parameter No. 6001 is not available. Local variables are always cleared to <null> when reset.
B.17.2 Differences in Diagnosis Display

None.

B.17.3 Miscellaneous

Series 0i-D allows you to customize the specifications related to the maximum and minimum variable values and accuracy by using bit 0 (F0C) of parameter No. 6008. When 1 is set in bit 0 (F0C) of parameter No. 6008, the specifications are the same as Series 0i-C. For details, refer to Section 16, "CUSTOM MACRO", in "USER'S MANUAL" (B-64304EN).

| 1 time | 166458 | 1664.58 | 16645 | 166.45 |
| 10 times | 1664589 | 16645.89 | 166458 | 1664.58 |
| When override is canceled | Metric input | Inch input | Metric input | Inch input |
| 1 time | 65535 | 655.35 | 6553 | 65.53 |
| 10 times | 655350 | 6553.50 | 65535 | 655.35 |

The minimum unit of feedrate is given by the expressions shown below. The value must be specified as an integer. No finer value may be specified.

- Fmin = P ÷ 7500 (mm/min)
- Fmin = P ÷ 1000 (mm/min)

A speed is specified according to the expressions shown below.

- F = N × P ÷ 7500 (mm/min)
- F = N × P ÷ 1000 (mm/min)

Setting range of torque data for torque control (11h)

- The setting range is as follows.

<tbody>
<tr>
<td>-999999999 to +999999999</td>
<td>0.0001 N m</td>
</tr>
</tbody>
</table>

Note on executing an absolute command from the program for an axis subject to PMC axis control during automatic operation

- [For Series 0i-D]
  When you switch to PMC axis control to execute a move command during automatic operation and then switch back to NC axis control to execute an absolute command from the program for the moved axis, that PMC command needs to be executed using a non-buffering M code.

  For example, when an absolute command is executed in a N40 block after PMC control is applied to Y axis, as in the example below, PMC axis control needs to be executed in a non-buffering M code (N20 block).

  O0001 ;
  N10 G94 G90 G01 X20. Y30. F3000 ;
  N20 M55 ; → Executes PMC axis control for the Y axis.
  N30 X70. ;
  N40 Y50. ;
  N50 M30 ;

  Execute PMC axis control as follows.
  1. After the output of the auxiliary function strobe signal MF for M55, start PMC axis control.
  2. Upon completion of PMC axis control, input the completion signal FIN for M55.
- [For Series 0i-C]
  Control does not need to be executed using a non-buffering M code.

# B.29 STORED STROKE CHECK

## B.29.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stored stroke check immediately following powering on</td>
<td>This function is always enabled for all axes.</td>
<td>It is possible to select whether to enable or disable the function on an axis-by-axis basis using bit 0 (DOT) of parameter No. 1311.</td>
</tr>
</tbody>
</table>
| | | **Bit 0 (DOT) of parameter No. 1311**  
The stored stroke limit check immediately following powering on is:  
0: Disabled.  
1: Enabled.  
**NOTE**  
This function stores machine coordinates using software and therefore imposes a burden on the system. Disable the function for those axes that do not require it. Movements made while the power is off are not reflected on the machine coordinate system immediately after powering on. |
| | Machine coordinates are set upon powering on.  
Absolute and relative coordinates are not set.  
(They are set when the absolute position detector is provided.) | Machine coordinates are set upon powering on.  
Absolute and relative coordinates are set based on these machine coordinates. |
| Y and J address specification using G22 | Not available. | Available for both the T series and M series. |
| Overtravel alarm | Stored stoke check 2 does not support bit 7 (BFA) of parameter No. 1300. Therefore, if an interference alarm occurs, the tool stops after entering the prohibited area. This makes it necessary to make the prohibited area slightly larger than actually necessary. | Stored stoke check 2 also supports bit 7 (BFA) of parameter No. 1300. Setting 1 in BFA allows the tool to stop before entering the prohibited area, thus eliminating the need to make the prohibited area slightly larger than actually necessary. |
| | **Bit 7 (BFA) of parameter No. 1300**  
If a stored stoke check 1, 2, or 3 alarm occurs, if an interference alarm occurs with the inter-path interference check function (T series), or if an alarm occurs with chuck/tail stock barrier (T series), the tool stops:  
0: After entering the prohibited area.  
1: Before entering the prohibited area. |
<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>

#### B.35.2 Differences in Diagnosis Display

None.
B.36 DATA SERVER FUNCTION

B.36.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory operation mode</td>
<td>- The memory operation mode is not supported.</td>
<td>- In the memory operation mode, the following operations can be performed for a program registered with the data server:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. Select the program on the data server as the main program and run it in the memory mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Call a subprogram or custom macro in the same directory as the main program on the data server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. Edit the program, including inserting, deleting, and replacing words.</td>
</tr>
</tbody>
</table>

In a 2-path system, a simultaneous external subprogram call (M198) of a data server program from both paths is:

- Allowed under the following conditions.
  [Storage mode]
  Both paths must use the same work directory.
  [FTP mode]
  Both paths must use the same connection host.

- Not allowed. Use the subprogram/custom macro call for the memory operation mode instead.

B.36.2 Differences in Diagnosis Display

None.
**B.37 POWER MATE CNC MANAGER**

### B.37.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4-slave display function</td>
<td>- By setting 1 in bit 0 (SLV) of parameter No. 0960, it is possible to split the screen into four windows, enabling up to four slaves to be displayed.</td>
<td>- Bit 0 (SLV) of parameter No. 0960 is not available. One slave is always displayed. When there is more than one slave, you switch the active slave by using the relevant soft key.</td>
</tr>
</tbody>
</table>

**Bit 0 (SLV) of parameter No. 0960**

- When Power Mate CNC Manager is selected, the screen:
  - 0: Displays one slave.
  - 1: Is split into four windows, enabling up to four slaves to be displayed.

### B.37.2 Differences in Diagnosis Display

None.
### B.38  
**CHUCK/TAIL STOCK BARRIER**

#### B.38.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overtravel alarm</td>
<td>- Bit 7 (BFA) of parameter No. 1300 is not supported. Therefore, if an interference alarm occurs, the tool stops after entering the prohibited area. This makes it necessary to make the prohibited area slightly larger than actually necessary.</td>
<td>- Bit 7 (BFA) of parameter No. 1300 is supported. Setting 1 in BFA allows the tool to stop before entering the prohibited area, thus eliminating the need to make the prohibited area slightly larger than actually necessary.</td>
</tr>
</tbody>
</table>

#### Bit 7 (BFA) of parameter No. 1300
If a stored stoke check 1, 2, or 3 occurs, if an interference alarm occurs with the inter-path interference check function (T series), or if an alarm occurs with chuck/tail stock barrier (T series), the tool stops:
0: After entering the prohibited area.
1: Before entering the prohibited area.

#### B.38.2 Differences in Diagnosis Display

None.
B.39 THREADING CYCLE RETRACT (CANNED CUTTING CYCLE/MULTIPLE REPETITIVE CANNED CUTTING CYCLE)

B.39.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return position after chamfering in multiple repetitive threading cycle (G76)</td>
<td>- The tool returns to the start point of the current cycle. For example, if it is the nth cycle, the tool returns to the position where the nth cut has been made.</td>
<td>- The tool returns to the start point of the threading cycle. This means that the tool returns to the position where it was before cutting, no matter how many cycles it has undergone.</td>
</tr>
<tr>
<td>Retraction after chamfering</td>
<td>- The specifications are as follows. [Acceleration/deceleration type] Acceleration/deceleration after interpolation for threading is used. [Time constant] The time constant for threading (parameter No. 1626) is used. [Feedrate] The feedrate set in parameter No. 1466 is used.</td>
<td>- Depends on bit 0 (CFR) of parameter No. 1611. When 0 is set, the processing is the same as Series 0i-C.</td>
</tr>
</tbody>
</table>

Bit 0 (CFR) of parameter No. 1611
In threading cycle G92 or G76, retraction after threading uses:
0: Type of acceleration/deceleration after interpolation for threading, together with the threading time constant (parameter No. 1626) and the feedrate set in parameter No. 1466.
1: Type of acceleration/deceleration after interpolation for rapid traverse, together with the rapid traverse time constant and the rapid traverse rate.

B.39.2 Differences in Diagnosis Display

None.
## B.40 POLAR COORDINATE INTERPOLATION

### B.40.1 Differences in Specifications

<table>
<thead>
<tr>
<th>Function</th>
<th>Series 0i-C</th>
<th>Series 0i-D</th>
</tr>

<tr>
<td>Move command when neither synchronous nor composite control is in effect</td>
<td>- Not prohibited.</td>
<td>- Make a selection using bit 7 (NUMx) of parameter No. 8163.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 7 (NUMx) of parameter No. 8163 When neither synchronous nor composite control is in effect, specifying the move command for an axis that is set with this parameter is: 0: Not prohibited. 1: Prohibited. (Alarm PS0353 is issued.)</td>
</tr>
<tr>
<td>Function</td>
<td>Series 0</td>
<td>-TTC</td>
</tr>
<tr>
<td>----------</td>
<td>--------</td>
<td>--------</td>
</tr>
</tbody>
</table>
| Behavior when an alarm is issued in relation to synchronous or composite control | Both paths are placed in the feed hold state. | Make a selection using bit 0 (MPA) of parameter No. 8168. **Bit 0 (MPA) of parameter No. 8168**  
If an alarm is issued in relation to synchronous, composite, or superposition control:  
0: Both paths are placed in the feed hold state.  
1: Only the path including axes related to synchronous, composite, or superposition control is placed in the feed hold state.  
For example, when synchronous control is exerted in one path, only the path that caused the alarm is placed in the feed hold state. The handling of the other path depends on the setting of bit 1 (IAL) of parameter No. 8100. |
| Behavior when overtravel occurs for an axis under synchronous or composite control | The synchronous or composite control mode is canceled. | Make a selection using bit 5 (NCS) of parameter No. 8160. **Bit 5 (NCSx) of parameter No. 8160**  
If overtravel occurs for an axis under synchronous, composite, or superposition control, the synchronous, composite, or superposition control mode is:  
0: Canceled.  
1: Not canceled. |
| Switch between synchronous control axis selection signal and composite control axis selection signal during automatic operation | The signals can be switched at any time. | Use an M code command. Specify a waiting M code (M code without buffering) before and after the M code. When synchronous or composite control is exerted in one path, specify an M or other code without buffering before and after the M code that starts or cancels the control so as to prohibit the look-ahead operation. |

### Synchronous control

| Item | Series 0|-TTC | Series 0|-D |
|------|--------|--------|
| G28 when the master axis is parking | When the reference position of the slave axis is not established, the machine coordinates are moved to the coordinates set in parameter No. 1240, completing the reference position return. | When the reference position of the slave axis is not established, alarm PS0354 occurs. |
| Update of the workpiece coordinates and relative coordinates of the slave axis under synchronous control | Make a selection using bit 4 (SPN) of parameter No. 8164. **Bit 4 (SPN) of parameter No. 8164**  
The workpiece coordinates and relative coordinates of the slave axis under synchronous control are:  
0: Updated.  
1: Not updated. | Bit 4 (SPN) of parameter No. 8164 is not available. The tool always behaves as when SPNx is set to 0 (coordinates are updated). |
<table>
<thead>
<tr>
<th>Item</th>
<th>Series 0i-TTC</th>
<th>Series 0i-D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out-of-synchronizaton detection when synchronous control is exerted in one path (1 is set in bit 1 (SER) of parameter No. 8162)</td>
<td>- Out-of-synchronizaton detection is not performed.</td>
<td>- Out-of-synchronizaton detection is performed.</td>
</tr>
</tbody>
</table>
| Manual handle interruption amount or mirror image mode for the master axis | - Always reflected on the slave axis.                                         | - Select whether to reflect the amount or mode on the slave axis, using bit 5 (SMIx) of parameter No. 8163.  
**Bit 5 (SMIx) of parameter No. 8163**  
During synchronous control, the manual handle interruption amount or mirror image mode for the master axis is:  
0: Reflected on the slave axis.  
1: Not reflected on the slave axis. |
| Automatic setting of a workpiece coordinate system for the slave axis at the end of synchronous control | - A workpiece coordinate system is not automatically set for the slave axis.  | - Make a selection using bit 6 (SPVx) of parameter No. 8167.  
**Bit 6 (SPVx) of parameter No. 8167**  
At the end of synchronous control, a workpiece coordinate system for the slave axis is:  
0: Not automatically set.  
1: Automatically set.  
The workpiece coordinate system to be set is determined by the machine coordinate values and the workpiece coordinate values of the reference points of the individual axes defined by parameter No. 1250. |

### Composite control

<table>
<thead>
<tr>
<th>Item</th>
<th>Series 0i-TTC</th>
